A Lecture

ON

RECURRENT EFFUSION INTO THE KNEE-JOINT AFTER INJURY,

BASED ON A SERIES OF 750 CASES.

Delivered at St. George's Hospital

y SIR WILLIAM H. BENNETT, K.C.V.O., F.R.C.S. ENG.,
SENIOR SURGEON TO ST. GEORGE'S HOSPITAL; SURGEON TO KING EDWARD VII. HOSPITAL, ETC.

GENTLEMEN,—Effusion into the knee-joint following upon jury direct or indirect is so commonly met with in actice that it is not difficult to obtain a large experience of it; indeed, any practitioner of a few ears' standing can hardly fail to have acquired a conderable practical knowledge of the condition. The 750 ses which I propose to consider now include those only which the effusion was recurrent either spontaneously or ter another injury, generally so slight that its effect upon normal joint would have probably been unnoticed. though the number of cases is at first sight large they nnot, of course, be regarded as an exceptional experience,
t it is thought that a consideration of such a series represent-
ears may afford some useful
common conditions, of which
in times like these, when the
ention of most people is concentrated upon the finding of mething that is new or rare, frequently looked upon as ing of poor account, merely, I suppose, because they are frequently met with. For the purpose of this lecture urrent effusion is held to mean a recurring effusion er an interval or intervals during which the joint, far as can be seen, has resumed its normal condition, ling the patients to consider themselves "quite ll," a limitation which necessarily excludes nearly all es in which a diagnosis of tubercle can be made with ficient certainty to justify its acceptance. Care has been en to be sure, as far as possible, that the injuries menned by the patients were really the cause of the original usion, all cases in which there was any doubt whatever ut this having been carefully excluded. The accompany- table (Table I.) gives a general idea of the character of cases dealt with.

I. CASES (509) ENTIRELY INDEPENDENT OF ANY CONSTITUTIONAL CONDITIONS.

(a) *Cases (428) in which the symptoms of internal derangement were very precise.*—In the 428 cases occurring under this heading are included some which I have already published elsewhere.[1] The difference shown in the implication of the sexes is, as would naturally be expected, very large, the proportion being 16 males to one female. This difference, although so large, is probably less than it would have been some years ago and unless the teachings of my later experience are at fault the increasing pursuit by women of athletic and various active exercises will before long largely increase the proportion on the feminine side. With
atient seen was nine years old
The left limb was concerned in
the cases, whilst in 15 (1 in 28½
of the total number) both sides were involved. With one exception the defect in the second knee followed that in the first after an interval, but in one case, a most remarkable one, both knees were found to be "locked" in a semi-flexed position after a fall downstairs, the patient having apparently alighted simultaneously on both knees; this case was subsequently operated upon, the anterior two-thirds of the
being found displaced into the
placed part was intact; on the
other things being equal, the
symptoms arising from lesions of the outer side of the joint were less acute than those connected with defects on the inner side; it was also noticed that when the outer semilunar cartilage seemed to be at fault the symptoms of pain and locking were referred to the popliteal space in at least half the cases. In all the cases operated upon in which the symptoms were referred posteriorly complete recovery followed the removal of the obviously displaced anterior part of the semilunar cartilage. In the total number of 428 cases the symptoms pointed to the inner side of the joint being concerned in 304, to the outer side in 113, and to both the inner and the outer side being involved in 11 (in two of these the diagnosis was subsequently confirmed by operation). 80 patients—i.e., about
20 pe
with the result seen
in Ta
the operative treat-
ment
ght the percentage
of cases operated upon may seem small, but it must be borne in mind that the patients seen were of all ages, some being too advanced in life to justify any pressure in the direction of operating. Some were in a

the
the

condition of health which negatived the propriety of active interference, others d [illegible] considerable number [illegible] to the radical treatment.

(*b*) *Cases (56) presenting no other symptoms than mere recurrence of effusion without noticeable further injury.*—This is a very interesting class. The complaints made were simply that the affected knee occasionally swelled up without any apparent reason and without inconvenience beyond a slight feeling of weakness. The original effusion had, with two exceptions, come on after a twist or sprain of so slight a kind that it attracted little or no notice at the time; in the two exceptions a blow from a cricket ball in c[illegible] case and a knock against the edge of a fender [illegible] the other accounted for the original lesion. In spite of the entire absence of other symptoms, in 12 of these cases which were subjected to operation the internal semilunar cartilage was found to be detached and displaced in five, the external in one, and in one of the cases both semilunar cartilages were displaced (*vide* Table II.) to such an extent that the displaced portions lay under the intercondyloid notch; in the five instances in which the internal [illegible] upied a similar position; [illegible] upon nothing abnormal could be detected in the joint. In two of th[illegible] in which nothing abnormal was found no recu[illegible] effusion had occurred after an interval of twc [illegible] it may fairly be assumed that the recovery wa[illegible] complete; in the three other cases the peri[illegible] which they were under observation was too short to [illegible] definite conclusion with regard to their recovery. [illegible] cases which were not operated upon 30 were tre[illegible] complete success by massage, exercises, electricit[illegible] the remaining 14 the ultimate effect of the same is not known.

TABLE II.—*Operations for Internal Derangement of the Knee-joint.*

Nature of operation.	No. of cases.	Sex.		Side.			Remarks.
		M.	F.	Left.	Right.	Both.	
Removal of pedunculated bodies, cartilage normal.	12	11	1	7	5	—	These cases all presented typical symptoms of internal derangement, occasional locking of the joint, &c.
Removal of internal semilunar cartilage.	56	54	2	41	13	2	Ditto, with the exception of five in which the only symptom was recurrent effusion.
Removal of external semilunar cartilage.	17	16	1	9	8	—	Ditto, with the exception of one case in which recurrent effusion was the only symptom.
Removal of both semilunar cartilages in the same knee.	2	2	—	1	1	—	In one of these there were typical symptoms of internal derangement, in the other there was recurrent effusion only.
Totals ...	87	83	4	53	27	2	—
		87		87			

In all these operations the abnormal parts were removed through a longitudinal incision from one and a half to two and a half inches long parallel with the ligamentum patellæ extending downwards to a point immediately below the line of the joint. In the two cases in which both th[illegible] were displaced they were readily removed [illegible] longitudinal incision; in one case the incision [illegible] the joint; in the other case it was on the inner side.

Two practical lessons may clearly be learned from these cases: (1) that in recurrent effusion into the knee-joint after injury, independent of constitutional conditions, when the usual methods of treatment have failed to effect a cure exploratory operation is indicated on the grounds of the probability of internal derangeme[illegible] extensive displacement of one or eve[illegible] may take place without the recu[illegible] ptoms which are commonly regarded as characteristic of the lesion.

The remarkable absence of characteristic symptoms in some of these cases of semilunar detachment seems to be due to the displacement being so great that the affecte[illegible] cartilages lie under the intercondyloid notch and so escap[illegible] in a great degree the liability to getting nipped between the bone ends. So far as my experience goes it may be said, speaking generally, that the cases in which the displacement is greatest give rise to fewer symptoms than those in which it is, although distinct, not very great, in consequence of the cartilage in the latter being more liable to be caught between the bones, a contention which receives further support from the fact that the trouble in the joint in many of these cases becomes less after a series of repeated attacks by which it is reasonable to assume the damaged structure has become [illegible] The position attained by some of [illegible] very remarkable. It is not, for an example, easy to understand the mechanism by which a diplacement like that shown in Fig. 6 is produced but much more extraordinary abnormality is sometimes seen. In a case in this hospital some years ago in which amputation was performed in consequence of [illegible] he knee-joint after an injury the internal [illegible] entirely wanting in its proper place was [illegible] ind the patella.

(*c*) *Obvious cases (21) of loose bodies in the joint.*—These call for little remark. The injury in each case was severe and was followed by excessive immediate swelling (from blood). In 14 of the cases operated upon a single fibrous loose body was found in each, the smallest mass being of the size of a horse-bean and the largest of the size of a cherry. In one of the two remaining cases two ovoid bodies were found; in the other the shape and structure of the body justified the diagnosis that it had been broken off the edge of the articular surface of the femur but no investigation was made to ascertain the point from which it came. The symptoms produced bore no accurate relation to the size of the loose body; speaking generally, however, the larger the body the less acute were the symptoms although the attacks in cases in which the larger bodies existed appeared to be more frequent.

(*d*) *Genu valgum (4).*—Although only four cases of this kind were met with in the series they are interesting because so far as n[illegible] into the joint in genu valgum is [illegible] of the disadvantage at which [illegible] existing under such conditions would seem to be placed in the event of injury. The injury in all the cases was indirect and in each a rapid increase in the deformity was said to have followed. The two cases operated upon were treated by osteotomy of the lower end of the femur for the rectification of the deformity, after which no further attacks of effusion occurred. In the remaining two cases operation was declined. The patients were aged 12, 13½, 14, and 15 years respectively.

OPERATIONS FOR INTERNAL DERANGEMENT OF THE KNEE-JOINT.

The principal points in relation to these cases are set down in Table II.

In none of the 87 cases was a more extensive exploration [illegible] d. I have [illegible] y in cases of this kind, as I have invariably been able to remove the original mechanical cause of defective movement or pain [illegible] , in the cases here [illegible] e detached cartilage [illegible]

cartilage is from an incision on th[illegible] therefore, in which there is [illegible] suspect detachment of both cartilage[illegible] xploration through an incision o[illegible] joint. [illegible]

thus obta[illegible] the restor[illegible] such an [illegible] very imp[illegible] operations. It is often laid down as an axiom that no operation for internal derangement [illegible] sidered complete in cases in [illegible] extension is defective unless [illegible] immediately possible; the movements of the joint, in fact, at the end of the operation should be as perfect as those of the opposite limb. I [illegible] cartilage this i[illegible] tainly not so in [illegible] movements—no [illegible] removal of the mechanical obstacle in the joint itself does not always allow of *immediate* normal extension which is, however, recovered gradually by the aid of massage and exercises.

The importance of an appreciation of this point lies in the fact that no matter what operation is performed or how freely the joint is opened there are a certain number of cases in which a resumption of normal movement does not immediately follow the removal of the objective abnormality [illegible] of all natural move[illegible] ich has a practical [illegible] ion, as the following case which came under my notice after ankylosis had taken place will show. A man with a long-standing displacement of a semilunar cartilage, the knee being fixed in a slightly bent position, was operated upon by a surgeon of repute, the lateral incision being employed and the displaced structure removed. Complete extension being still impossible the joint was explored by the transpatellar method with a view to finding the obstacle to free movement. Nothing further was found and the defective movement remained as before; suppuration unfortunately followed and a stiff joint in the same slightly bent position resulted. The transpatellar exploration was obviously superfluous here and had the operator been content with the slighter operation complete movement would have been almost certainly obtained by the usual means—at least such is the conclusion that my experience in these cases leads me to. I very much doubt whether any obstacle to movement in conditions of this sort could exist which the finger introduced in the manner I have mentioned would fail to detect, assuming, of course, that it is endowed with sensation of average acuteness. An additional point of interest connected with the method of operation was very plainly demonstrated by the condition of the parts in every one of the cases operated upon in which the cartilage was displaced—viz., that not only would it have been useless but impossible to fix effectually in their normal place any of the displaced cartilages with the least prospect of their remaining in their restored position, a fact which, considering the number of cases dealt with, ought, I think, to be sufficient to dispose of the idea which I understand still exists, with some people, that a truly displaced cartilage can be *effectually* stitched in position. The result in all the cases but two was perfect, the mechanics of the joint being entirely normal. In one of the two exceptions the movements were slightly restricted as the patient declined to submit to the necessary manipulation; the defect, however, was not sufficient to interfere with ordinary occupations and no lameness was apparent. The other defective example occurred in a boy in whom the power of complete extension has not been quite regained, but as the operation in his case is comparatively recent (about eight months) a perfect result may yet ensue.[3]

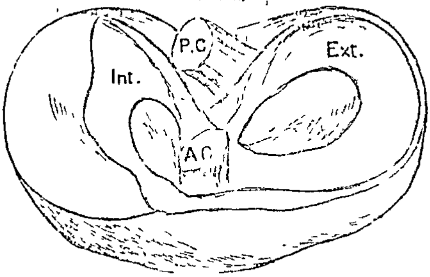
Conditions of the damaged cartilages—The injuries to the cartilages arranged themselves into seven groups which will be perhaps most readily understood from the following diagrams. Each diagram shows the condition found in an operation and forms the basis of a group in which are included all the cases presenting injuries either identical with, [illegible] depicted. It [illegible] generally, in cases affect[illegible] the structure itself is m[illegible] r torn) than is the case with the internal cartilage. This is precisely what [illegible] on to the knee in jumping, and apart from the damage to the structure itself the violence resulting in detachment of the external cartilage was, with the few exceptions in which the internal cartilage was split or torn, greater than that leading to displacement of the opposite cartilage—a fact which is quite in accordance with what would be anticipated on anatomical grounds.

II. CASES (241) INFLUENCED BY CONSTITUTIONAL CONDITIONS.

As would naturally be expected, the existence of a constitutional dyscrasia exercises a considerable influence in these (1) in leading to the occurrence of symptoms from very slight causes and (2) in rendering recovery difficult or impossible unless the constitutional conditions be treated or, at all events, taken into account—a matter also of consequence in relation to prognosis.

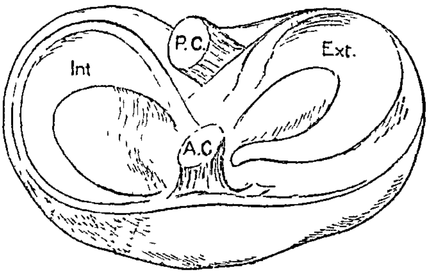
(*a*) *Osteo-arthritis* (107).—*It is, I am aware, open to* question whether cases of this type should be included in a series like that I am considering, but as in all of those which I have included here the condition undoubtedly followed upon injury and the effusion was recurrent after an interval or intervals of apparent recovery they may fairly be considered as coming within the category. All when first coming under observation were very early instances of osteo- [illegible] the diagnosis of osteo- [illegible] rtainty after repeated [illegible] owed by some charac- [illegible] ne initiating injury was [illegible] rect—e.g., a twist or sprain. Of the cases operated upon in only two was a loose body felt before the treatment; in the remainder attacks of acute pain, in three cases leading to sudden falls, led to operative investigation; in all the cases explored the loose bodies were found and removed through a longitudinal incision at the inner side of the joint. As would naturally be expected, males were affected largely in excess of females, about four to one, the right knee being concerned more frequently than the left. When the second knee became affected it was invariably the result of some twist, strain,

FIG. 1.



Anterior two thirds of cartilage displaced inwards; anterior extremity remaining attached (33 cases, 30 affecting the internal cartilage and three the external).

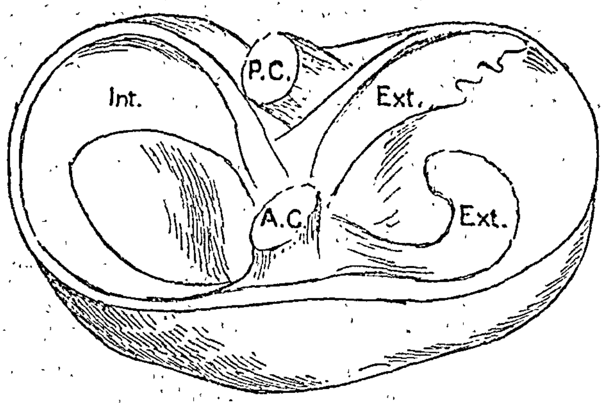
FIG. 2.



Anterior half of the cartilage displaced inwards; anterior extremity torn away from its attachments (20 cases, 18 affecting the internal cartilage and two the external)

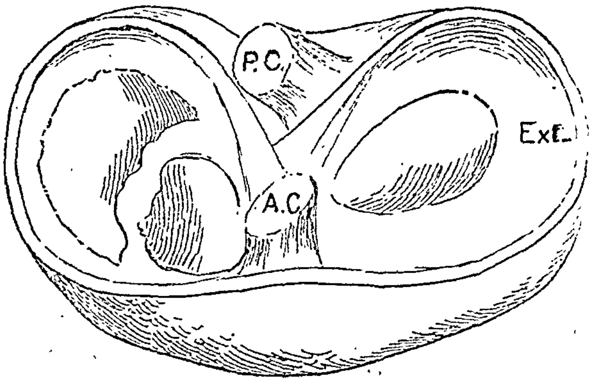
[illegible]

FIG. 3.



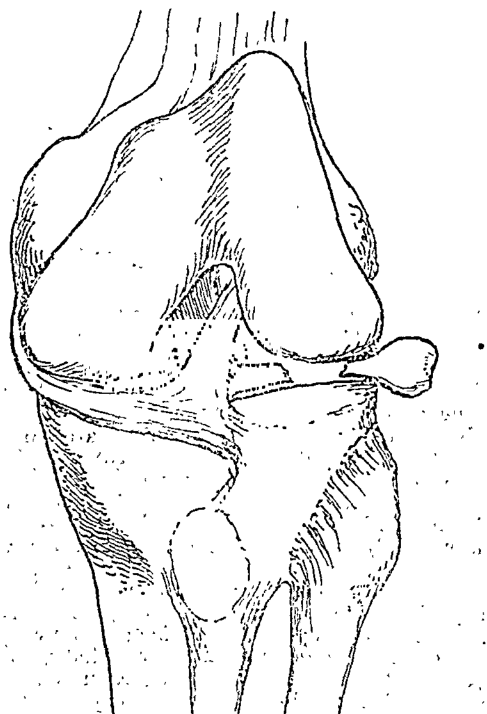
Cartilage torn across near the centre; posterior part of the anterior segment displaced inwards in some of the case; in the remainder the posterior segment was the displaced part (ten cases, three affecting the internal cartilage and seven the external).

FIG. 4.



Cartilage split longitudinally over the middle two-fourths, the inner portion remaining attached at both ends and displaced inwards (five cases, two affecting the internal cartilage and three the external). In each case the marginal portion of the cartilage was loosened but not displaced.

FIG. 5.

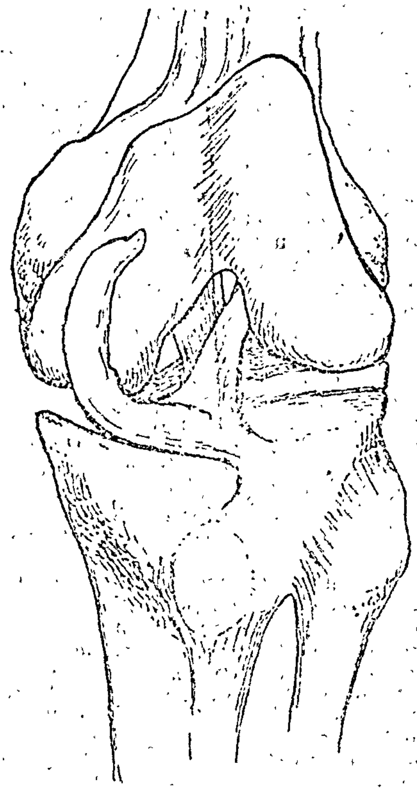


Cartilage torn from its connexions anteriorly and pushed outwards, thus producing a tumour readily felt under the soft parts (three cases, one affecting the internal cartilage and two the external).

or stumble in attempting to "save" the knee already involved.

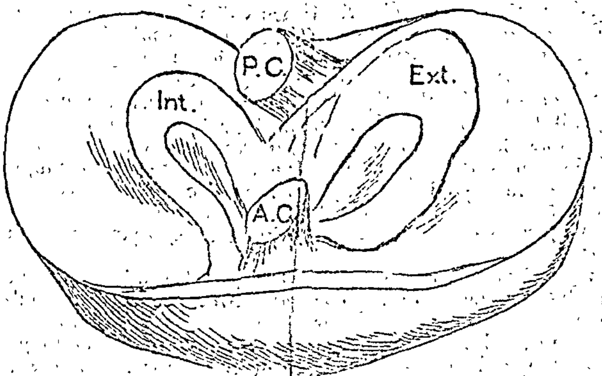
With regard to the treatment of these cases nothing seemed to have more than a palliative effect excepting the radiant heat-bath massage and electric vibration which in 23 cases of comparatively recent origin appeared to effect an actual cure. In a certain percentage the pain at the onset of effusion was very great but as a rule rapidly subsided. When persistent a gentle application of the thermo-cautery over the seat of intensity was followed by remarkable relief excepting in the cases where a loose body accounted for the symptoms.

FIG. 6.



Cartilage torn from the lateral connexions and turned up on to the articular surface of the femur (two cases, both involving the internal cartilage).

FIG. 7.



Both cartilages torn from connexions and greatly displaced inwards (two cases). In one case both cartilages were detached at the anterior extremities, in the other the anterior end of one cartilage remained attached.

(*b*) *Rheumatism and gout* (30).—Nothing of much practical account arises out of these cases. Those which were undoubtedly influenced by a gouty tendency all commenced after a direct injury; the rheumatic cases followed an indirect injury as a rule; in the gouty instances the skin over the joint showed the usual redness and acute sensitiveness to pressure; the effusion was rapid and excessive; in two instances, had the history of attacks of acute gout in other joints not been forthcoming, suppuration in the joint might easily have been suspected; indeed, in one case incision was seriously considered and would certainly have been carried out if the gouty history had not been so distinct. In the cases in which rheumatism was clearly a strong factor a cure was, as a rule, effected by the usual constitutional treatment combined with massage. The operations were performed for the relief of acute pain due to tension; incision appeared to possess no advantage over aspiration in the relief of the pain, whilst the healing of the wound was in both cases of incision slow and in one more reaction followed than was quite desirable; in the future, therefore, in such cases I shall be content to aspirate the joint, other means for reducing the tension having failed.

(c) *Syphilis* (42).—In the cases included in this category the longest period between the original infection of the constitutional disease and the receipt of the injury causing the effusion into the knee was 28 years, the shortest period being three years; in all the syphilis appeared to have been properly treated and to have been "cured." The injury in all the cases was direct and as a rule slight; the right knee as would be expected was much more frequently involved than the left (29 to 13). In no case was permanent benefit derived until a course of antisyphilitic treatment was adopted. In some it was the inveteracy of the condition which led to the searching inquiries which elicited the history of syphilis.

(d) *Gonorrhœal rheumatism* (28).—All the patients in this class had suffered from "rheumatism" after gonorrhœa within three years but were, so far as they knew, well until the injury started the effusion into the joint; the injuries were in the majority indirect and in each case the affected knee had been concerned in the gonorrhœal infection. In one case in which both knees were injured at the same time, one very severely, the other slightly, the former recovered rapidly and completely, whilst the latter, which had been affected at the time of the gonorrhœa, developed very inveterate recurrent attacks of effusion. In 17 of the cases there was an obvious gleet, although the patients were unaware of the fact. The operations were performed to relieve tension and acute pain. Aspiration effected the object as perfectly as incision, whilst it was less inconvenient, as there was, of course, no wound which required treatment.

(e) *Malaria* (18).
the number at first
portion came under
In all the cases the
malaria for some years and in none had any joint affection been noticed until the receipt of an injury causing in the first instance some swelling of the articulation. In the cases classified here, although the joints appeared to have regained the normal condition, succeeding attacks of "fever" were accompanied by effusion into the joint which had been injured. This behaviour of joints under the influence of malaria after injury is new to me, although it may possibly be familiar to those who are more intimately associated with tropical disease. In the case operated upon an incision was made as the extreme tension of the joint and the very high fever suggested the possibility of suppuration. The wound healed kindly.

(f) *Hæmophilia* (3).—These cases are of no particular interest with the exception of that which was aspirated in which after three attacks of effusion following injury a fourth occurred with so much tension and fever that it became desirable to ascertain the nature of the fluid; it was only upon the withdrawal of a large amount of blood that the diagnosis was made; the joint refilled but not to the extent it had done before the puncture. In none of the cases had there been any other joint involved: in two there was the usual family history; in one (that which was aspirated) no history of hæmophilia was forthcoming.

(g) *Quiet effusion in young people* (13).—In THE LANCET of Feb. 23rd, 1901, p. 527, I called attention to a passive effusion principally into the knee and ankle joints which is prone to occur in young girls during adolescence if the menstrual arrangements are irregular and especially if they are delayed in their onset. In ordinary circumstances upon the regulation of the catamenia the joint trouble disappears and no further inconvenience arises from it. In the event, however, of any injury being received whilst the quiet effusion is present the symptoms do not always subside with the rectification of the menstrual defect but may give trouble for a considerable time afterwards as a recurrent effusion. Of such a kind are the cases included under this heading. The injury, as a rule, was not severe, but the greatest difficulty in treatment arose when it was direct—e.g., a knock of the knee against the leg of a table.

Taken as a whole I cannot help thinking that this series of 750 cases affords a good deal of useful information, although it has been, of course, impossible, in the time at my disposal, to attempt anything more than a very superficial discussion of some of the obvious points which suggest themselves in connexion with the cases under consideration.

A Clinical Lecture

ON

A SIMPLE METHOD OF SEPARATING AND COLLECTING THE URINE WHICH IS SECRETED BY EACH OF THE TWO KIDNEYS.

Delivered at St. Bartholomew's Hospital,

BY W. BRUCE CLARKE, M.A., M.B. OXON., F.R.C.S. ENG.,
SURGEON TO, AND LECTURER ON SURGERY AT, THE HOSPITAL.

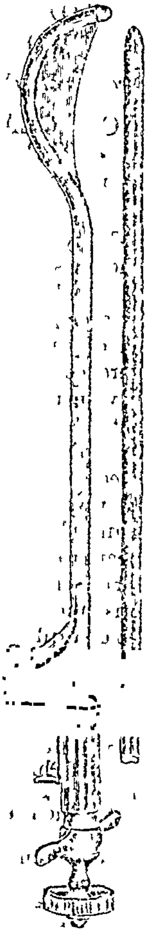
GENTLEMEN,—Many have been the attempts which have been made in times past to discover a method by which the urine of each of the kidneys could be collected and submitted to examination, with a view to ascertain the pathological condition of each of those two organs before any operative interference was attempted. It is needless to recapitulate the various methods that have been tried and so far found wanting. Some years ago methods of blocking the orifices of each of the ureters in turn were resorted to. This was effected either by the pressure of a bag of mercury, which was introduced by the urethra, or by employing a pair of forceps shaped somewhat like a lithotrite by means of which the mouth of each ureter in turn could be seized. Latterly attempts have been made to catheterise the ureters, a procedure which demands no small amount of skill and practice in the operator and even in trained hands is in some cases liable to failure. Small wonder that none of these have come into a general use. A method which is uncertain is worse than useless, for it is liable to engender a false sense of security and has more than once induced a surgeon to operate when, as the operation has proved, his patient should never have been submitted to such a procedure.

The instrument which I have in my hand[1] to-day (see illustration) has none of these objections. It is simple to introduce when reasonable skill is employed, practically infallible in action, innocuous so far as the patient is concerned, and does not require an anæsthetic for its employment. Needless to say, it is simple in construction—every good piece of mechanism is. The Luys separator, for such is its name, converts the bladder for the time being into two halves by means of a vertical septum. Each half of the base of the bladder receives the urine from the corresponding ureter and delivers it by a separate channel into a glass tube on its own side. Thus we can watch the urine flowing from each kidney as easily as if each ureter opened separately on the outside of the body. The instrument consists of two catheters placed side by side. They are fastened together by a screw and can easily be taken apart. Placed between them is a chain, actuated by a screw in the handle. The curve of this instrument is, you will see, more semicircular than that of the ordinary catheter. Before introducing it into the bladder its middle portion, to which the chain is attached, is covered by a thin rubber sheath. As soon as the instrument has reached its destination the handle, which actuates a screw, is turned round and the chain is tightened so that instead of lying in its semicircular groove between the two catheters it is stretched tightly across the semicircle. It forms, in other words, its diameter instead of lying along its circumference. The rubber sheath is by this manœuvre stretched so that it forms a vertical semicircular partition which divides the base of the bladder into two halves and each of these delivers its contents into its corresponding catheter. If slight pressure is exerted on the base of the bladder there is no difficulty in preventing the urine from one kidney from mingling with that of its fellow, in other words, complete intravesical separation is attained.

---

[1] I am indebted to Messrs Arnold and Sons, West Smithfield, for the use of the accompanying block.

When the instrument has been introduced the patient is kept in a recumbent position with the pelvis flat on the bed or couch. If he turns on his side it is, of course, obvious that an overflow will be liable to take place from one side of the septum to the other. In some instances it is necessary to carry on one's observations for half an hour, or even more, before a sufficient quantity of urine has been collected to enable one to draw an accurate inference as to the pathological condition of each of the kidneys, but as a general rule ten minutes are enough. As soon as a sufficient quantity of urine has been collected the handle is unscrewed and the *chain drops back into its place, the rubber* covering follows suit, and the instrument is withdrawn in the usual way. If you have found any difficulty in [illegible] this difficulty will at once vanish when you have had [illegible] instrument in your hands for a couple of minutes.



There is another form of this instrument in which the septum is formed in a slightly different manner. I need not do more than allude to it. The form [illegible] is, I believe, simpler and less liab[illegible] There is only one caution that I would give you with regard to its use. It is a somewhat delicate piece of mechanism and if you wish it to work efficiently see that it is carefully cleaned with a little spirit each time after use and then it will not be liable to get rusty a[illegible] that smoothness which is so neces[illegible] to be obtained. See also that yo[illegible] rubber sheaths.

If I relate to you some of [illegible] employed this instrument you will at once realise how important an aid it is to diagnosis and treatment.

The first instance in which I made use of it was one, as you will see, of obstructive suppression—that is to say, a case in which one kidney had been practically destroyed by a calculus and in which complete obstruction was being threatened owing to the impending blockage of the opposite ureter. Such cases when they are typical are not very difficult to detect but in this instance no history could be obtained of a previous attack of renal colic or any evidence of even the probability of such an attack. The illness from which the patient was suffering had come on suddenly in a man, aged 46 years. He had been seized without [illegible] pain in the region of the left kidney and ureter which had temporarily yielded to fomentations, hot baths, sedatives, and rest in bed. Each time one of these attacks supervened there was an arrest in the secretion of urine, though it could hardly be said to amount to complete suppression. There had been some six or seven attacks in the past three weeks. The longest one had lasted three days and the shortest only a few hours but latterly the pain had invaded both loins. The urine was highly coloured, tinged with blood sometimes, and there was a little pus in the specimen which I examined; it had a specific gravity 1014, gave an acid reaction, and contained a trace of albumin. The day before I saw the patient he had had a severe attack over the region of the right kidney and both loins were tender to touch. His temperature was a little raised and he was evidently ill. Though on the whole it seemed most probable that a stone in the pelvis of the l[illegible] the clue to his symptoms the rece[illegible] right kidney region made the condit[illegible] a matter of considerable doubt. In [illegible] I introduced the separator, and within a few seconds urine began to issue from the left catheter. It was not until nearly half an ounce had come from this side that urine began to issue from the [illegible] quarter of an hour quite enough ha[illegible] purposes of examination and the ins[illegible]

The appearance of the urine from the two sides was absolutely different. That from the right side was small in amount (scarcely more than a teaspoonful) whilst three-quarters of an ounce had come from the left kidney. The examination of the two specimens yielded the following result. The urine from the right kidney was slightly alkaline and contained a [illegible] that from the left kidney was a[illegible] ous or albumin. It was now [illegible] of doubt that the kidney [illegible] kidney and [illegible] contained a [illegible] kidne[illegible] so damaged by some previous attack as practically to be useless.

An operation was performed a few days later on the left kidney. The ston[e] [illegible] was extracted from its pelvis. A [illegible] still occasionally t[illegible] left side. I have suggested that the right kidney should therefore be explored and if necessary removed, for it is not only a useless organ but is liable to infect its neighbour by giving rise to a left-sided ascending pyelitis. So far the patient, who does not realise the danger of the situation, is unwilling to submit himself to a second operation.

The next case in which I employed this instrument was [illegible] of a patient in whom one kidney (the left) had been [illegible] years previously. I was anxious to test [illegible] for [illegible] of the instrument and to make sure that no urine could pass [illegible] le of the bladder to the other. Urine i[illegible] right catheter and [illegible] from the left side. I was, I confess, surprised to [illegible] difficult it was, even when the separator was loosely inserted, to get any urine to issue from that side of the bladder in whic[h] [illegible] was functionless. The case [illegible] effected was proved beyond doubt.

[illegible] case in which the separator was employed [illegible] There had been [illegible] which was in [illegible] the country, [illegible] by no means a successful one, and when I saw the patient her kidney was undoubtedly fixed, but it was quite low down and almost touched the crest of the ilium. There was in addition a condition of hydronephrosis which she at least attributed to the operation. There was no need to apply the separator to prove the presence of the hydronephrosis, as it was obvious without it. As, however, I had advised an operation for the refixation of the kidney in a higher position and for the relief of the hydronephrosis, I was anxious to have an exact record of the flow of urine both before the operation and subsequently to it and accordingly the separator was introduced with the following result. On two occasions no urine at all passed from the right ureter into the bladder for upwards of half an hour b[illegible] that time freely secreted by [illegible] bladder by the left ureter. [illegible] a third occasion, a period being chosen when the right kidney was very fully distended and therefore presumably liable to empty itself. For fully a quarter of an hour no urine came from the right kidney but the left secreted freely. At the end of the quarter of an hour the patient, who was suffering [illegible] nded [illegible] pain [illegible] issue from the right side in a small but quite continuous stream, two ounces being passed in very little more than five minutes. *Meanwhile the left kidney ceased to secrete at all.* I was unable to extend the sitting as long as I had wished because the patient was in considerable discomfort notwithstanding that the right kidney was slowly emptying itself, but it was curious to observe that the left kidney did not secrete one drop of urine during the time that the right kidney was emptying itself. The urine which was secreted by the hydronephrotic kidney only contained about 1·2 per cent. of urea —less than half the percentage secreted by the healthy organ.

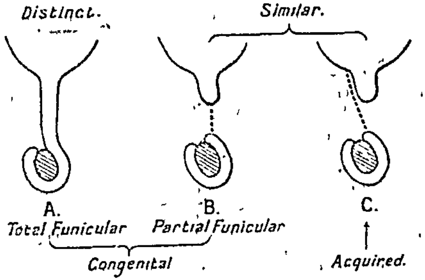
A few days later the right kidney was explored by me and found [illegible] lumbar fascia but much lower [illegible] has already been described. [illegible] section it was freed from its bed and refixed as high up in the abdomen as was possible. The pelvis of the [illegible] bougie was passed right t[illegible] stricture or blockage of any [illegible] pelvis was accordingly closed by a catgut suture. The kidney itself appeared to be fairly healthy. The lumbar incision was likewise closed, a small drain being inserted at its lower end in case any leakage should take place. For a few days a slight amount of urine was passed by the wound but by the end of a week the leak had completely ceased and the patient felt perfectly comfortable. The separator was introduced at this period and again five days later. [illegible] same on both [illegible] hough slightly [illegible] the left side [illegible] h issued from [illegible] bandage and [illegible] at the kidney [illegible] e beyond any [illegible] operation was entirely successful and the right kidney was secreting nearly 2 per cent. of urea as against 1·2 per cent. before operation. I see no reason to doubt that time will restore [illegible] healthy condition.

[illegible] e of this instrument. The [illegible] pus from time to time with [illegible] hough pointing to the right lumbar region were not sufficiently marked to make it absolutely certain which of the two kidneys was affected. She [illegible] e but the urine, [illegible] was too opaque [illegible]. The separator [illegible] blue in a pill [illegible] result was a [illegible] e naturally. It [illegible] ply stained with [illegible] same character was voided. It was tested for urea and found to contain less than ½ per cent. The diagnosis was consequently placed beyond doubt and the right kidney was removed a few days later. It was little more than a bag of [illegible]. The upper [illegible] removed at [illegible] value of a [illegible] portance of [illegible] which it is capable of affording us. I could relate many others but I prefer that you should see the instrument itself made use of in the wards and watch the advantageous results which we obtain by its use. By these means you will better appreciate the points I have endeavoured to impress on you in this lecture.

ON THE PATHOLOGY AND TREATMENT OF THE HERNIÆ OF CHILDREN AND THEIR RELATION TO CONDITIONS IN THE ADULT.

BY R. HAMILTON RUSSELL, F.R.C.S. ENG.,
SURGEON TO THE ALFRED HOSPITAL, MELBOURNE; CONSULTING SURGEON TO THE MELBOURNE HOSPITAL FOR SICK CHILDREN.

IN THE LANCET of August 20th last[1] there appeared the report of a post-graduate lecture on the subjects indicated in the above heading by Mr. E. M. Corner, a surgeon whose position, while it invests his utterances with the weight of authority, will also render it assured that the views he advances are carefully weighed and founded on a solid scientific basis. It is therefore with no little astonishment that I discovered that the conclusions to which Mr. Corner has been drawn by his experience of hernia in childhood are so diametrically opposed to those at which I and many others have arrived as to be hopelessly irreconcileable. My own views on this subject have been very amply set forth in a series of articles which have appeared in this journal during the last five years;[2] these Mr. Corner has either not read, or having perhaps read them he has deemed them [illegible] an endeavour should be made [illegible] the truth lies, a view with whi[illegible] cordially agree than he. I ask, therefore, permission to state once again, as concisely and as courteously as possible, not merely my opinions, which are of no value, but the evidence on which those opinions have been built up; evidence which it is open to all surgeons to test for themselves and which I believe to be unimpeachable in its conclusiveness.



The dotted lines in B and C indicate the obliterated portion of the funicular process.[2]

The issues are very definite and are easily stated. All authors, until quite recently, have agreed that inguinal hernia in childhood may be (1) *congenital*, dependent on total patency of the processus vaginalis; (2) *funicular*, dependent on partial patency of the processus vaginalis; and (3) *acquired*, not dependent on the processus vaginalis at all but caused by incompetence of the abdominal wall. The characters of these three varieties are shown in the accompanying diagram. I have substituted for the careless and inexact terms of common usage, "congenital" and "funicular," my own nomenclature of "total funicular" and "partial funicular" respectively, for reasons which are obvious and which have been already explained at length in these columns on two previous occasions.[3] Now it will be noted that while the first two forms A and B are etiologically identical, being both congenital, C differs from them in being recent or acquired. Curiously, however, A and B, the two congenital forms, present so marked a contrast one from the other that the tyro could never fail to distinguish them, while, on the other hand, B and C, which have nothing in common in point of origin, are yet so much alike as virtually to be indistinguishable from one another. And now the question at issue emerges very clearly; it is as follows. Mr. Corner, on the one hand, places all the herniæ of childhood in which the sac is distinct from the tunica vaginalis in the category of the acquired (C). I, on the other hand, place them all in the category of the partial funicular (B) and deny the existence of the acquired (C). I find myself in somewhat of a difficulty through the fact that Mr. Corner has made no reference at all to Class B. I presume this is only the result of an inadvertence and I shall assume that the existence of such a class is admitted by him, in addition to the acquired (C). This circumstance, however, does not affect the real point at issue, which turns solely upon the question of the existence or non-existence of acquired hernia (C) in children; and I would point out that the answer we give to this question is not a mere matter of academic or pathological interest, it is the most important question with regard to hernia from a practical standpoint that can be advanced for debate: I will go further and say that it is the *only* question of supreme moment that the subject in its elementary form presents. The reason of its predominating importance is this. The large majority of herniæ in children admittedly have a sac which is quite distinct from the tunica vaginalis and all such must belong to either (B) the partial funicular (congenital origin) or (C) the acquired (of non-congenital origin). But how are they to be distinguished individually? It obviously cannot be done and nobody has ever suggested any method of doing it. Now it stands to reason that if in operating on any individual case of hernia the surgeon is unable to tell whether it is of congenital origin belonging to Class B or whether it is of acquired origin and due to defect of the abdominal wall and, as such, belonging to Class C, he is in the position of being virtually in complete ignorance of the etiology and nature of the affection he is treating and it is therefore impossible that his procedure should be based on any sound rational principle. This startling corollary from the usually accepted views as to the etiology of hernia is inevitable and the resulting disability to our efforts at precise scientific treatment will be irremediable and permanent unless a close and well-directed scrutiny of the whole subject should make it evident that the accepted views are defective and susceptible of revision and alteration.

---

[1] [illegible] 1904, p. 511.

[2] [illegible] May [illegible] 0th, 1900, p. 1123

The first very simple question that will arise from the foregoing statement is this: if the large number of herniæ that are comprised in the two groups B and C are indistinguishable from one another what evidence is there that both groups actually exist? Why do they not all belong to either B on the one hand or C on the other? There must surely be some evidence forthcoming—evidence that is independent of the mere naked-eye appearance—to show that certain individual cases must be relegated to the category of Class B while others, with equal certainty, must be classed under C. Nothing of the kind! The evidence demonstrating the funicular origin of individual herniæ proving them to belong to Class B is abundant and constantly recurring. On the other hand, concerning Class C, amazing as the statement may seem, no particle of evidence, direct or indirect, has to my knowledge ever been adduced to show that any single case of hernia in a child should be placed in that category. The existence of acquired hernia in childhood has been entirely taken for granted; it has been the purest assumption from beginning to end.

Now I am aware that this last statement is of the nature of negative evidence and I quite recognise that even though no evidence has ever been adduced in favour of the acquired origin of hernia that does not prove that none ever will be or that hernia may not be acquired. We need not, however, be concerned with any question as to the value of negative evidence, for the positive evidence in support of my position is abundant and conclusive. There is one test which, if equally applied to all cases of hernia in childhood may, I presume, be trusted to distinguish between those of congenital origin (B) and those of acquired origin (C) and that is simple removal of the entire sac by operation. I imagine it will be conceded that if in a case of hernia resulting from incompetence of the abdominal wall (acquired hernia, Class C) the peritoneal sac be simply ligatured and removed and nothing be done to repair the supposed defect in the walls of the inguinal canal, the operation must of necessity prove futile and the hernia will recur; and conversely, if after such simple operation as I have described the hernia does not recur we may, *ipso facto*, conclude that the hernia in question was not due to any defect in the abdominal wall and therefore cannot be classed as an acquired hernia (C). In the course of the last eight years I have performed the operation for inguinal hernia in young children 143 times (with two deaths). I have not systematically endeavoured to trace all these cases with a view to publish statistics in this paper, because for a variety of reasons that course could hardly strengthen the evidence. Suffice it to say that for several years past no other operation than the simple one I have mentioned has been performed by my former colleagues at the Melbourne Children's Hospital and the result of their experience has been to verify the statement I made five years ago that in the inguinal hernia of childhood if the sac be completely removed recurrence will not take place. In actual practice it is exceedingly probable that an occasional recurrence will be met with, because all operators are not equally experienced and skilful and the operation varies in point of difficulty and is always difficult for a beginner, but, as I shall point out directly, the fact of occasional recurrence does not invalidate my contention as to the etiology of hernia. As regards my own series the bulk of my patients were operated upon prior to three years ago, when my work at the Children's Hospital ceased. Of these cases only one, to my knowledge, recurred. In this case the hernia reappeared about four months after the operation and was evidently due to incomplete removal of the sac, for a second operation performed with perhaps more thoroughness 18 months ago has not been followed by recurrence. These 143 cases, I may remark, were the result of no process of selection; they represent the total number of the cases of hernia in childhood that came under my care during the period named. In no case with the exception of a few very young infants was a truss advised. All cases were subjected to operation, virtually without discrimination.

It is perfectly clear that whatever view we may take as to elaborate operations based on the principle of closing the canal in order to prevent hernia no difficulty or doubt is possible as to the deduction we are permitted to make from so simple an operation as this. It is self evident that if as the result of operation the hernia does not recur the cause of the hernia must have been removed; and if the operation has consisted solely in removal of the sac, then the sac must have been the cause of the hernia in every case; and these will therefore all belong to Class B. On the other hand, the fact of recurrence after operation will not necessarily prove that the case in question was an acquired hernia (C), because recurrence will also take place after operation on the congenital form (B) provided the removal of the sac be incompletely carried out. In brief, when simple removal of the sac has been performed for hernia, non-recurrence will prove that the case was of congenital origin (B); but recurrence will *not* prove that it was of acquired origin (C). If now by the light of this reasoning we take a large number of cases of hernia in young children treated by simple removal of the sac, and we find that recurrence is only an excessively rare event, we shall surely arrive at the conclusion that to prove any single one of those cases to have been of acquired origin will at least demand evidence of the most stringent and incontrovertible nature, such as I am unable to conceive, and such as certainly has never to my knowledge been even suggested.

Difficult to combat as this evidence is it is by no means the only evidence I am able to bring forward in support of my contention that the inguinal sac in children is invariably congenital—i.e., either total or partial funicular. If any

[3] THE LANCET, Nov. 18th, 1899, p. 1353, and March 12th, 1904, p. 707.

man who has the opportunity of frequently removing hernial sacs from children will make a point of inspecting [illegible] removal he will [illegible] ntly recognising [illegible] ure with as much facility and precision as that with which the shepherd is enabled to distinguish the characteristic faces of his flock. I have on former occasions gone into this question with minuteness; suffice it to mention here that he will find all sorts of variable characters that could not be produced in an acquired sac, such as bilocular or multilocular sacs, sacs with marked sacculations and with occasionally a sacculus closed over forming a cyst, sacs showing imperfect division into one or more segments, sacs imperfectly closed at the end, and so on. It is rare for me to remove a hernial sac without being able to point out to onlookers after its removal the characters that indicate its congenital origin. I may mention incidentally that the sacculation I refer to here should not be confused with the sacculation that is observed in the case of a genuinely acquired hernial sac, as in ventral hernia occurring in the seat of an operation wound. In the latter case the irregular outline of the sac is due to its having had to force its way through a maze of cicatricial tissue and the most casual observer will see at once that there is no true similarity between the two things.

Thus I hold it proved that so long as we employ a method of reasoning by sound induction the evidence will be all on one side and yet there will be many who are not yet convinced. It is worth while to digress for a moment to seek an explanation of the reason for this mental attitude with regard to hernia. If we were to be asked to state our conception of the origin of hernia in a general and elementary way we should probably do it somewhat in this wise: "In the normal state there are two opposing forces at work, on the one hand the intra-abdominal pressure, on the other hand the retentive power of the abdominal walls; in this contest so long as the retentive power holds its own there will be no hernia, but when the intra-abdominal pressure overcomes the retentive power at any one point hernia results." Fair as this statement may seem, there is an implied fallacy, for it distinctly creates the impression that there must be some sort of equality between the two opposed forces, whereas the truth is that the preponderance in strength of the retentive power of the abdomen over the intra-abdominal pressure is so enormous that the part which this latter force *unaided* could be capable of playing in the production of hernia may be set down as a *quantité negligeable*. This is a matter that does not appear to lend itself very readily to [illegible] observation will afford [illegible] rmation. It shows, for [illegible] quiescent state of the abdomen the interior pressure is to all intents and purposes *nil*, while it is only during effort that it can be said to exist at all, and even then the rise of the intra-abdominal pressure is trifling in comparison to the muscular effort expended. Take a case of undoubted acquired hernia—viz., that form of hernia that occurs after abdominal operations where the abdominal wall has been left open for drainage, as in cases of appendicitic abscess. Here, in a region very close to the inguinal region, we see an area from which the support of the three strong muscles is taken away, with the substitution merely of a thin layer of cicatricial tissue. And yet so feeble is the intra-abdominal pressure that the occurrence of protrusion is a process that extends over months. Could any better illustration be offered to show the enormous preponderance of the retentive power of the abdomen over the feeble intra-abdominal pressure? It may, however, be urged that the inguinal region and the appendix region are very different, which is true; but can it for a moment be suggested that the inguinal region is constructed in a manner so extraordinarily feeble as to reduce it to anything like the low level of retentive efficiency possessed by the web of cicatricial tissue in the appendix region? Again, there is no more striking illustration of this point than is provided by the subject under discussion. The presence of a peritoneal sac is, of course, ruinous to the retentive efficiency of the abdominal wall at that spot. Were the balance between the intra-abdominal pressure and the retentive power under normal conditions at all lightly held the presence of a peritoneal sac would mean hernia inevitably. That it does not do so is attributable to the fact that the efficiency of the abdominal musculature is so much in excess of the requirements that it may often be enabled to prevent the descent of hernia in spite of the presence of a sac. In this fact lies the very obvious explanation of the so-called curing of hernia by means of a truss, a perfectly simple and intelligible phenomenon, absolutely innocent of any excuse for the mystery that is often thrown around it.

As has been formerly pointed out, not only is the inguinal region not weak, but such is the construction of the canal by virtue of the sphincteric mechanism of the arched fibres that the very effort which is required to create an intra-abdominal pressure calls forth a commensurately increased resistance in the inguinal region.[4] Let us, however, in spite of all this, assume for the sake of argument that the intra-abdominal pressure could conceivably produce an acquired hernia. Where would the hernia appear? Clearly at the weakest spot in the abdomen. Now the femoral ring differs from the inguinal canal in being completely devoid of any protecting mechanism. It is a ring with rigid walls, a genuine "opening," which the inguinal canal is not, and it is devoid of any protecting musculature such as is owned by the inguinal canal. It would appear almost to have been designed specially in order that hernia might descend into it. There is no comparison whatever between the inguinal and femoral regions in regard to their capacity respectively for resisting the pressure from within. Now if the view which has been put forward associating hernia in children with distension from dyspepsia were correct, it would necessarily follow, first, that the number of femoral herniæ would preponderate largely over inguinal; secondly, and still more remarkable, that when inguinal hernia did occur it would always be preceded by, or at least associated with, a femoral or two femoral herniæ. There is no escape from this simple deduction, but how utterly it is negatived by clinical experience I need not say. Moreover, I can find not the slightest reason for believing, either from my own experience or the experience of members of the staff of the Children's Hospital, that there is even the most visionary association between the dietetic troubles of childhood and hernia. This section of the *discussion may be briefly summed up thus*: Seeing that the inguinal region is far more strongly fortified against the occurrence of acquired hernia than the femoral region, it is inconceivable that acquired inguinal hernia should occur without an associated femoral hernia, and conversely, when inguinal hernia appears while the femoral regions remain intact the inguinal hernia cannot be of the acquired type and can only be due to the presence of a congenital sac. This is tantamount to saying that acquired inguinal hernia does not exist. The case of femoral hernia, however, has not been disposed of; I am again conscious that if I have to admit that femoral hernia can be and is acquired although inguinal hernia cannot be I shall fail to convince [illegible] so very similar th[illegible] as to the soundn[illegible] inherent [illegible] that an agency which was causative [illegible] the other no[illegible] m to be. On [illegible] ears. There is abundant evidence that femoral hernia, too, is [illegible] acquired, and that the sac is a [illegible] the primitive pleuro-peritoneal [illegible] to traverse afresh ground which has already been trodden upon two previous occasions in these columns,[5] suffice it to say that the evidence in favour of the congenital origin of the femoral sac appears to me as conclusive and satisfactory as that which relates to inguinal hernia.

Finally, a most important generalisation. If we conclude that neither inguinal nor femoral hernia is ever acquired and that the intra-abdominal pressure is far too feeble an agency to produce hernia in either of those situations, it would seem that the theory of acquired hernia may be dismissed altogether, for it must be admitted that our observations on inguinal and femoral hernia will cover the cases of the rarer forms of abdominal hernia—e.g., the obturator, ischiatic, hernia into the triangle of Petit, &c. We therefore regard the term "acquired" as being appropriate to the traumatic form alone, whereas all ordinary forms of abdominal hernia we regard as congenital in origin and dependent on the presence of a developmental diverticulum.

from the primitive pleuro-peritoneal cavity, which in the inguinal canal alone appears to be constant and to serve a purpose and to merit a special name. The relationship existing between the hernia of childhood and that of adult life is a matter into which I will not now enter at any length. I will merely observe that some years of work at the Melbourne Children's Hospital led me to the views on hernia in childhood which I have expressed above, views which have been confirmed and strengthened by increased experience and by the concurrence not only of my former colleagues and many surgeons in this country but also of able observers elsewhere.[6] Three years ago my sphere of work was suddenly transferred to a large general hospital where numerous opportunities have been afforded me of operating on adults. As a practised operator on children I at once looked, and have continued to look, closely for evidences of some distinguishing features between the hernia of adult life and that of childhood. I have found not the slightest evidence of any *etiological* difference. In adult life some modifications are presented which I may term incidental, due to long duration, &c. The operation invariably performed is, *in principle*, identical with that which I perform in children, but with certain differences in technique; and the results will, I believe, also prove to be substantially identical. This, however, is a matter that merits more detailed treatment than can be accorded to it here.

In an early part of this paper I pointed out the hopeless disability under which operators must of necessity be condemned to labour if it be true that inguinal hernia may be either congenital or acquired, and I would point out that a precisely similar disability has afflicted writers on hernia with an even more paralysing effect. It is notorious that the subject has always presented many difficulties and inconsistencies to which we have allowed ourselves to become resigned as inexplicable. In text-book accounts authors have been driven irresistibly to the alternative courses of either silently evading difficulties or admitting their inability to explain them. This will continue to be so until authors recognise that the fundamental statement with which they usually open their articles, to the effect that "hernia may be either congenital or acquired," is completely erroneous; that it is an error, moreover, which must of necessity foil all attempts to harmonise the multitudinous aspects and phenomena presented by the affection.

Melbourne, Australia.

THE INFLUENCE OF RAINY WINDS ON PHTHISIS.

By WILLIAM GORDON, M.A., M.D. CANTAB.,
F.R.C.P. LOND.,
PHYSICIAN TO THE DEVON AND EXETER HOSPITAL, ETC.

IN earlier papers I have shown that in Devonshire the mortality from phthisis is much greater in those districts which are exposed to the prevalent strong rainy winds than in those which are sheltered from them and that these winds are injurious to phthisical patients.[1] In the present paper I propose to show, first, that in many countries exposure to prevalent strong rainy winds is accompanied by increased phthisis mortality; secondly, that in the most successful health resorts for phthisis strong rainy winds are not prevalent; and, thirdly, that the influence of these rainy winds on the prevalence of phthisis is more powerful than that of any other influence except marked difference of race and, in some communities, of occupation.

PART I.—PREVALENT STRONG RAINY WINDS AND PHTHISIS MORTALITY.

Since great differences exist in the condition of wind and rain in different belts of latitude the following regions will be separately considered: A, Northern region of westerly winds—N. of 30° N.; B, southern region of westerly winds—S. of 30° S.; C, region of the north-east trade winds; D, region of the south-east trade winds; E, so-called equatorial calm belt; F, so-called calm belt of Cancer; and G, so-called calm belt of Capricorn. The Faröes, the Falklands and Iceland will be considered separately last.

A. *Northern Region of Westerly Winds.*

England.—The prevailing rainy winds are south-westerly, westerly, and north-westerly. Davidson's account of the phthisis distribution may be summarised thus (see Table I.).[2]

North Wales	2·57

For the ten years 1871 to 1880 the region of maximum prevalence of phthisis stretched along the western side of the country from Cumberland to Cornwall, extending into Northumberland, whilst the minimum prevalence was found in the counties of Rutland, Worcester, Hereford, Stafford, and Shropshire. The low death-rates of these latter five counties could not be explained on the ground of sparseness of population or of agricultural occupation; in Rutland where phthisis was least prevalent the acreage per person was the same as in North Wales where phthisis was most prevalent; in Staffordshire, in spite of its potteries, the mortality was less than in Bedfordshire which was purely agricultural. In Cornwall tin-mining, in Lancashire and the West Riding cotton and woollen manufacturing, and in North Wales slate-, copper-, and lead-mining doubtless increased the mortality from the disease but in Wales generally injurious industries did not account for its high death-rates since these were nearly as great in districts where there were no injurious occupations. Davidson thought that soil largely determined the differences in the death-rates of the agricultural counties. But he summed up thus: "It ...... appears that no complete explanation can be given of the g [illegible] f phthisis in England. We have h[illegible]ce of a zone similar to that which [illegible] Provinces of Germany and at certain altitudes in Switzerland in which phthisis, for reasons not yet understood, attains a high degree of prevalence." Now if we exclude Northumberland, the high phthisis death-rate of which is doubtless due largely to its industries and its crowded towns, the distribution of phthisis in England from 1871 to 1880 was very much what it should be if exposure to rainy wind is taken into consideration. The western counties are the most exposed and have the highest death-rate. Rutland, which is sheltered, Worcester, Hereford, Stafford, and Shropshire, which are perhaps the most sheltered counties from all westerly winds, have the lowest death-rates. This distribution of phthisis is [illegible] hthisis [illegible] —viz., 1861–70, 1871–80, and 1881–90. As the high death-rate in Wales might be thought to be due to race, Table II. is appended, showing that within Wales itself the death-rate is heavier in the districts exposed to westerly winds.

The figures are taken from the Registrar-General's returns.

that the two lowest death-rates are in Kinross and Nairn, both well sheltered from the rainy winds; that, except Elgin, Forfar, and Edinburgh (of which the first is open to the north-west, whilst the other two contain very populous towns), the eastern counties have relatively low death-rates, whilst the western counties as far north as Argyll have all relatively high death-rates. North of Argyll, on the west, the counties either run across from east to west or, like Inverness, include great inland areas with marked local shelter and therefore can scarcely be used for comparison. Of the western counties with high death-rates it must, however, be remembered that Renfrew includes part of Glasgow.

Ireland.—The configuration of the country makes its … westerly … extremely … ease from west to east in the regular way it does in Great Britain.[3] Also the most populous and industrial centres are on or near the eastern coast. Perhaps, in view of the greater ease of comparing their shelters and exposures, a comparison of urban districts may give more definite results than a comparison of wider areas. Ten years' records are available for 16 such districts. (See Table IV.) Of the two great populations of Dublin and Belfast, Dublin, most open to the rainy winds, although less industrial than Belfast, has the higher death-rate. Of the other towns those with the lowest death-rates, Drogheda, Dundalk, Kilkenny, Newry, and Armagh, are all in the eastern part of the island and more or less sheltered from the rainy winds. Lurgan and Lisburn, although in the eastern counties, have a high death-rate, but they are by no means sheltered and are great linen manufacturing centres. In spite, therefore, of the peculiar

difficulty of an inquiry into the influence of rainy wind on phthisis in Ireland, indications are not wanting that exposure to rainy wind and relatively high phthisis death-rate tend to correspond.

Norway.—The prevalent strong rainy winds of Norway are the south-west, west, and north-west. On the south and south-east coasts the south and south-east winds are also rainy.[4] The greatest mortality from phthisis (see Table V.) is found in the south-western counties where the fiords and valleys afford ready access to the south-west, south, and south-east winds. Of the only other counties with heavy mortality South Trondhjem appears to afford exceptionally easy access to the north-west wind, but of Finmarken I have too little information to speak. The counties protected from sea gales, either by the narrowness of their winding fiords or by their inland position, suffer least from the disease.

Sweden.—The position and surface of Sweden make the inquiry in that country difficult and I have no very recent figures. Davidson says that in 1886 and 1887 phthisis was more fatal in the centre and south than in the north and was most fatal between 58° and 60° N.[5] This is the region of the lakes and is the part most open to rainy winds from the Atlantic.[6] The figures given by Davidson, however, relate only to towns. (See Table VI.)

TABLE VI.—*Death-rates per 1000 from Phthisis in Towns of Sweden, 1886 and 1887.*

—	Number of towns.	Population, 1886.	Death-rate, 1886.	Death-rate, 1887.	Mean

South of Lat. 58°	8	214,798	2·81	2·86	2 84

From Davidson's Geographical Pathology, vol. i., p. 40.

Denmark.—A map for which I have to thank the kindness of Dr. Rördam, illustrating the phthisis death-rates in the towns, shows that a line drawn along the north-west coast of Europe and produced so as to cross Denmark divides it into a northern area in which the prevalent south-west wind is a sea wind and therefore relatively rainy, and a southern area in which the south-west wind is a land wind and therefore relatively dry.[7] All the highest death-rates, except that of the capital, lie north of this line, and the only low mortalities north of the line are seemingly under shelter of the east coast. Also, as the rainfall lessens from west to east the phthisis mortality in the towns also decreases from west to east.[8]

Germany.—The chief rainy winds of Germany are south-westerly, westerly, and north-westerly. Most rain falls in June, July, and August, during which the north-west wind becomes relatively common.[9] Schlockow has shown[10] that tuberculosis is much more fatal in the western than in the eastern provinces, the high mortality in the lower Rhine towns being specially remarkable, and Hirsch points out that this cannot be explained as due to hurtful industries because the smaller rural districts in the western provinces show a very high death-rate. Davidson says:[11] "Whatever may be the explanation, the distribution area of phthisis in Germany is in a marked degree determined by longitude." Schlockow's figures (see Table VII.) for the rural populations of the Prussian provinces are all the better for the present purpose that they refer to the years 1875 to 1879, before the conflicting influences of growing industries with increasing wages in some provinces and of special precautions against phthisis, in the same provinces or in others, came into operation. When these figures are looked at it becomes instantly apparent that the provinces most exposed to the prevalent rainy winds suffer most from phthisis.

These figures are taken from Hirsch's Geographical and Historical Pathology.

Switzerland.—The rainy winds of Mid-Europe are the south-westerly, westerly, and north-westerly.[12] Parts of Switzerland must also get rainy south-east winds from the Adriatic.[13] The mountain ramparts of Switzerland shut out these winds except at certain points and therefore the assessment of shelter and exposure to rain-bearing winds in Switzerland becomes difficult. Moreover, the winds as they sweep over the maze of mountain and valley must obviously bend and interlace in a confusing manner. Also, since the prevalent wind on the Rigi appears sometimes to be north-west when that on the loftier Säntis is south-west,[14] it seems likely that the warmer southern currents float over cooler northern currents. Therefore every district requires a specially careful investigation. Thanks to the kindness of Dr. W. R. Huggard, who lent me his valuable maps of the Grisons,[15] I have been able to examine that canton in detail. I have also travelled over most of it. The result, which I shall deal with more fully presently, shows almost everywhere that complete exposure to rainy winds corresponds with a relatively high mortality from phthisis.

France.—In the recent report of the French Tuberculosis Commission Professor Brouardel states that there are three chief centres of tuberculosis in France[16]—viz., (1) Paris and the neighbouring departments extending through the north-east corner of France; (2) Brittany with Mayenne; and (3) from Doubs through Lyons to Gard. The method by which the figures for the departments have been obtained is, as Professor Brouardel points out, crude,[17] but he evidently considers this broad conclusion correct nevertheless. The rainy winds of France, west and north-west of the Cevennes, are from the Atlantic, therefore westerly and north-westerly everywhere. In the north-west and north of France, south-west winds must be also rainy, but from the south-west departments and the centre of France, Spain and the Pyrenees cut off the rain from this quarter. South and south-east of the Cevennes, according to Hann, belongs climatologically to the Mediterranean countries,[18] and gets rainy winds from the south-south-west, south, and south-east. The higher altitudes of the French Alps, however, must still get rain from westerly Atlantic winds. When these relations of the rainy winds are borne in mind Professor Brouardel's three centres can, I venture to think, be roughly accounted for.

There are, broadly speaking, (1) a belt of high phthisis mortality all along the north west and north coasts of France, reaching a considerable distance inland and corresponding to a region where probably north west, west, and south west are all wet winds, (2) a broad interior region of lower phthisis death rate, over which the south west winds from Spain must be relatively dry, (3) a region of high death rate along the valleys of the Rhone and Saône, where rainy winds from the Atlantic and the Mediterranean may be supposed to meet, but (4) a low death rate in the Alps, the valleys of which are protected from all rainy quarters, (5) the Pyrenean valleys have also a low death rate, in spite of their heavy rainfall, because their direction shelters them also from the west

Corsica has most phthisis, Dr Trotter informs me,[19] on its western side, which is the more exposed to rainy winds It must, however, at the same time be mentioned that the western is the poorer district

Spain —The heaviest rainfall in Spain is on its northern and north western coasts, where the Atlantic gales are fully felt The least rainfall and least wind are on its south-eastern coast at Malaga and Valencia[20] According to Dr Zerolo's figures, quoted by Dr J Cleasby Taylor (see Table VIII), the phthisis death rates in these two regions are as strikingly different as their wind and rain Barcelona, which appears to get more rainy wind than the districts further south, has a higher death rate from phthisis than they have

TABLE VIII —*Average Death rates per 1000 from Phthisis in Northern and South-eastern Coast Provinces of Spain during Five Years, from Zerolo's "Tuberculoso y Climatherapeutica" in order of Ascending Phthisis Mortality*

Bilbao	193 233	2·66	Malaga	509 171	1·11
			Murcia	457,765	1·25

Italy —The chief rainy winds appear to be south westerly, westerly, and north westerly, and the rainfall is heavier on the western side of the peninsula[21] The south east seems to be a rainy wind only round the head of the Adriatic[22] The figures recently given by Dr H T Bulstrode (see Table IX) for the distribution of phthisis in the provinces[23] correspond strikingly with the conditions of wind and rain

TABLE IX —*Average Death rates per 10,000 from Phthisis in the Provinces of Italy from 1888–94 and 1897–99, from Dr Bulstrode's Milroy Lectures*

Provinces west of the Apennines from north to south		Provinces east of the Apennines from north to south

Calabria	5·4	Abruzzi	6·7
Inland		Apulia	8·1
Umbria	8·7	Basilicata	4·0

Northern Africa —Algiers exposed to a prevalent north west rainy wind,[24] has a considerable death rate in its coast towns[25] Tunis sheltered by the extremity of Mount Atlas from north west winds, is extremely dry[26] and tuberculosis is stated to be less common amongst the French troops there than in any other corps of the French army[27] The Delta of the Nile, where rainy winds from the north west and north are common[28] contrasts markedly with the country above Cairo in having a considerable death rate from phthisis

Persia —Persia is a very dry country[29] and Sir Hugh Adcock informs me that phthisis there is "not at all common"[30]

Kashmir —Kashmir is shut in by great mountains on all sides and is therefore comparatively windless[31] Mr A Neve tells me that, except in the very crowded and insanitary capital, phthisis is "almost unknown"[32]

Japan —The distribution of phthisis in Japan is interesting Dr W W Colborne of Hakodate has been so kind as to send me a map of the distribution of phthisis in the cantons Before consulting Hann's Climatology on the meteorology of Japan, I tried to discover from the phthisis distribution what is the prevalent strong rainy wind and decided that the north-west must be the wind in question On referring to Hann I found that it is so[33] The north west wind of winter is in Japan a very violent, constant, and rainy wind There is, however, another rainy wind—the south-west of summer This brings a heavy rainfall but its force is "incomparably" less than that of the winter north west

United States of America —For the whole of the United States I can only obtain the table given by Davidson (See Table X)[34] This only deals with one year and only gives

TABLE X —*Showing for the Rural Districts of Regions of the United States the Proportion amongst Females of Deaths from Phthisis in 1000 Deaths from Known Causes (Billings, quoted by Davidson)*

the Mississippi valley is approached. There rainy south-west winds become frequent and extend over the Eastern States. On the Atlantic seaboard rainy winds from easterly directions are common and strong. The Appalachian range in the Eastern States must have rainy winds from both east and west. In Florida, according to the Storm Plates in Bartholomew's Meteorological Atlas, the wind is lighter. Bartholomew's Atlas also shows well the distribution of rainfall in the States.[36] Corresponding to this distribution of rainy wind the census for 1880 gives the following distribution of phthisis mortality (Table X.). The Pacific coast has a high death-rate, though it should be remembered that it has not been divided as the Atlantic coast has been in the census, so that it is impossible to say whether the mortality south of San Francisco is different from that further north; also it must be borne in mind that South California is a much-used phthisis sanatorium and that therefore many cases are imported. The Cordilleran region of raised valleys and plains within the western rampart is relatively free from phthisis. So are the western plains under the lee of the Rockies. As the Mississippi is approached the phthisis death-rate increases and becomes greatest over the Appalachians and on the Northern and Central Atlantic coast. Florida, in spite of a heavy rainfall and partly negro population,[37] has a relatively low mortality. The table of wind velocities in America, given in Table XI., has a certain value, although it must be remembered that such *average* estimates take no account of the occasional force of the wind. Thus no indication is given by the figures that the wind on the Pacific coast, although more continuous than on the Atlantic, is weaker[38] —a fact probably of great importance in respect of its influence on phthisis. Neither does it show the dryness or raininess of the gales. Storm frequency in different parts of the Eastern States, as shown in Bartholomew's Atlas, corresponds with the phthisis mortality distribution to an extent which is at least suggestive. Where storms are rare and rain is heavy and where storms are frequent but rainfall is light, phthisis is uncommon. Where storms are frequent and rainfall is heavy phthisis is prevalent. The Atlas shows the same in the case of Italy.

TABLE XI.—*Constructed from Solly's "Medical Climatology" and Davidson's "Geographical Pathology."*

B. The Southerly Region of Westerly Winds.

The rainfall of this region is generally less than that of the preceding region and is more apt to occur in sudden deluges comparatively soon over. It may therefore be said that prevalent strong wet winds are less marked than in the northern region of westerly winds and it is interesting to observe that phthisis appears to be correspondingly less frequent. It must not, however, be forgotten that the countries in this region are comparatively newly settled.

Australia.—Victoria is more exposed to rainy winds than either New South Wales or South Australia and has, according to the statistics quoted by Dr. Bulstrode,[39] a higher death-rate. (See Table XII.)

TABLE XII.—*Deaths per 1000 from Phthisis in Victoria, New South Wales, and South Australia, from Dr. Bulstrode's Milroy Lectures.*

Victoria...	1·45	1·33	1·23
South Australia... ...	1·06	0·99	0·87
New South Wales ...	0·99	0·86	0·79

South Africa.—The prevalent rainy winds for the eastern part of the colony, about which alone I have information, are south-easterly.[40] Along the coast exposed to this wind phthisis appears to be common.[41] According to Clemow, it is "alarmingly prevalent amongst the natives" in Pondoland, Tembuland, and Transkei, "in spite of their open-air life."[42] Across the mountain range. however, which cuts off the south-east wind from the interior, in the Karoo, in British Bechuanaland, and in the district bordering on the Orange Free State phthisis is said to be uncommon.[43]

South America.—Under the lee of the Andes in Argentina there is a region very free from rainy winds.[44] Phthisis is said to be uncommon there, although on the coasts of both Chili and Argentina it is prevalent.[45]

C. Region of the North-East Trade Winds.

The regions both of north-east and south-east trade winds unfortunately include few places where satisfactory statistics exist. Deaths are so often uncertified even in towns, mixture of races introduces such confusion, and an apparent tendency of the disease to prevail in coast towns in the tropics is so general that safe conclusions can rarely be drawn. I shall, therefore, only refer to those statements which seem to deserve special consideration. The north-east trades blow steadily all the year as moderate breezes. Gales are uncommon. At the sea-level the trade wind is dry, but rain may be very heavy when the wind is forced upwards by rising land. The region in which they continually blow may be said to begin at 25° N. latitude and to extend to the equatorial calm belt. This belt begins about 10° N. latitude in our summer and about 5° N. latitude in our winter in the East Atlantic and perhaps in the East Pacific. In the west of both oceans the trade wind probably blows right up to the equator.

Abyssinia.—The statement that phthisis is rare on the plateau of Abyssinia has had some stress laid on it.[46] If true, this may perhaps be accounted for by the fact that this plateau is surrounded by high mountains which must form an effectual wind screen

[44] Bartholomew's Atlas shows a very low rainfall.

[45] Davidson: Op. cit., vol. ii., pp. 983. 975, 976.

[46] Hirsch: Op. cit., vol. iii., p. 206.

Jamaica —Davidson states that during 1897 and 1898, whilst the death rate from phthisis for the whole island was 1·7 per 1000, the country district of St Elizabeth, on the south western coast sheltered from the trade wind, had so low a death rate as 0·09 per 1000[47]

Mexico —The wind movement is very small at the city of [illegible] [48] Phthisis amongst Euro[illegible] l is said to be seldom seen, [illegible] the Atlantic and Pacific coasts[49]

British Guiana —Georgetown, fully exposed to the north-east trade, blowing directly and forcibly on to the coast with a heavy rainfall[50] has a heavy death rate[51]

D Region of the South east Trade Winds

These are only a little stronger than the north east They may be said to blow continually between 25° S and the equator I [illegible] altitudes v [illegible] heavy rain [illegible] valley the eastern rampart of which must shut out the trade wind Jauja and Tarma, in Peru, lie in a "well sheltered valley"[53] Arequipa, on the western slope of the Andes, has very little wind or rain[54] La Paz in Bolivia has a rainfall of less than 10 inches[55] and is well sheltered from south east wind by mountains On the other hand, phthisis is common all along the Brazilian coast, which is directly exposed to the trade wind and has a heavy rainfall[56]

E The So called Equatorial Calm Belt

This belt appears to be well marked in the East Atlantic Ocean Along the Gold Coast, according to Dr W T Prout, phthisis is not common[57] In the colony of Lagos I have learnt, through the kindness of the late Governor, Sir William MacGregor, that it is rare[58] For the rainy part of the year both colonies lie within the belt of equatorial calms and light variable winds The season, in which the colonies are outside this belt is dry All the year round a south west wind makes itself felt,[59] but this appears to be only a gentle breeze

So called "Calm Belts" of Cancer and Capricorn

There seems a great deal of evidence that between the latitudes of 25° and 35° N and S a belt of calms and light variable winds about 5° broad encircles the globe and moves to and fro with the seasons Between 30° and 35° N and S the year is divided between this calm belt and the westerly winds, and the latter probably so far neutralise the effect of the former that for the present purpose this part of each belt may be placed (as has been done) in the regions of westerly winds But between 25° and 30° N and S the calm belt alternates with the gentle trade winds, and these latitudes ought to be characterised by relatively less phthisis owing to relative rarity of rainy wind Moreover the calm belts are dry belts which should make the relative rarity of phthisis even more probable In the southern hemisphere the belt of Capricorn runs more or less horizontally round the earth but in the northern hemisphere the continent of Asia is said to draw the belt [illegible] north It will, I think, [illegible] spondence between these [illegible] exists in those countries where it can be investigated

F The "Calm Belt" of Cancer

Florida and a small strip of the *Gulf Coast of North America* have been shown to have a low phthisis death rate in spite of a largely negro population and a heavy rainfall The *Canaries* have a lower death rate than any part of Spain —viz, 0·7 per 1000[60] *Egypt between Cairo and Assouan* is nearly free from phthisis[61] Further east the position of the belt becomes uncertain

G The "Calm Belt" of Capricorn

South Africa —British Bechuanaland, the Orange Free State, Basutoland, and part of the Transvaal, in all of which phthisis is almost unknown,[62] as well as Zululand and Natal, *in which it is uncommon*,[63] lie *between 25° and 30°*

Australia —The Darling Downs of Queensland perhaps the best climate for phthisis in the continent[64] lie within the belt They are remarkable for the absence even of the hot winds which other parts of the interior experience[65]

The Faroes, the Falklands, and Iceland

Lastly, there are three countries which have been grouped together and said to constitute a strong objection to the conclusions as regards rainy wind and phthisis arrived at elsewhere—viz, the Faröes the Falklands and Iceland

Of these the *Faroes* have, Dr Rordam informs me, not a low mortality from phthisis, as has been supposed, but one probably as high as Denmark generally[66]

The *Falklands*, where phthisis has been said to be very rare, have a low rainfall—only about 20 inches; the prevailing winds are westerly at all seasons (see Table XIII)[67] and the inhabitants have built their dwellings almost everywhere in shelter as can be seen from the Government Survey Map Stanley, the only town, is built on the shores of a land locked inlet, sheltered from every wind

TABLE XIII —*Frequency of Winds in the Falkland Islands (Hann)*

—	N	NE	E	SE	S	SW	W.	NW	Calms
Spring and summer	9·6	6·3	5·3	8·0	24·7	52·0	46·7	25·7	2·7
Autumn and winter	14·0	4·0	7·0	3·7	13·3	30·0	61·7	37·0	13·0

Iceland, where phthisis is said to be uncommon has a moderate rainfall of about 28 inches in its western parts from which the statements come relating to phthisis rarity, where the capital lies and where the bulk of the population appear to dwell The prevailing winds are from the east (see Table XIV)[68] and having to cross the high tableland of the centre of the island are dried and broken when they descend to the western coast

TABLE XIV —*Frequency of Winds in Reykjavik and Stykkisholm, Iceland (Hann)*

—	N	NE	E	SE	S	SW	W	NW
Winter	9	25	22	12	9	17	4	2
Summer	12	13	20	13	11	11	8	12
Year	12	19	22	13	10	13	5	6

Thus, in none of these three instances can it be said that prevalent strong rainy wind coexists with rarity of phthisis and the objection based on them does not hold

Summary of the Foregoing

In all these different parts of the globe therefore, prevalence of *strong rainy winds appears to be remarkably* associated with increased prevalence of phthisis whilst absence of such winds seems to correspond strikingly with rarity of phthisis

THE CULTIVATION OF TRYPANOSOMA OUT OF THE LEISHMAN-DONOVAN BODY UPON THE METHOD OF CAPTAIN L. ROGERS, I.M.S.

By G. C. CHATTERJEE, M.B.,
ASSISTANT BACTERIOLOGIST, MEDICAL COLLEGE, CALCUTTA.

(*With Coloured Illustration.*)

FOLLOWING the method of my teacher, Captain L. Rogers, I.M.S., for cultivating Leishman-Donovan bodies in citrate of sodium solution I have succeeded in developing trypanosoma from the Leishman-Donovan bodies.

The patient from whom the blood for making the culture was taken by spleen puncture was an inhabitant of Sylhet. He gave a history that three members of his family had died recently from fever with enlarged spleen and œdema of the legs. He had been suffering from the fever for six months and was very anæmic. The spleen reached down to the umbilicus but the liver was not enlarged. There was no marked pigmentation. The temperature of the patient at the time of the puncture was 102° F.

The following procedure was adopted for taking the blood from the patient and for cultivating the parasites found in it. The skin over the region of the spleen was cleaned with soap and water and then washed with a 1 in 20 carbolic lotion. A five cubic centimetre syringe, sterilised in a 1 in 20 carbolic lotion and washed in boiling water, was used for puncturing the spleen. After drawing out the blood it was emptied into a test-tube containing one cubic centimetre of 5 per cent. citrate of sodium (the test-tube with the citrate solution being previously autoclaved at 115° C.). The test-tube wsa then placed in a beaker which was put inside an ice-box.

A stained slide preparation of the blood made on the first day showed a good number of distinct Leishman-Donovan bodies, from three to four being found in a single field. On the next day a stained specimen made from the citrated blood showed great increase of the parasites in number, so much so that from 200 to 500 bodies could be counted in a single field instead of the three or four seen on the first day. The parasites showed increased development; they were distinctly larger in size. The micronucleus was distinctly increased in size and was less circumscribed and was elongated in shape. The micronucleus was situated at one end of the oval body instead of being in the middle. The contents of the body of the parasite were more granular; numerous dividing ones were seen. No flagellate forms were found on this day.

On the third day the stained slide from the blood showed a remarkable appearance.[1] In many of the fields were seen elongated Leishman-Donovan bodies with a thick flagellum. In some portions of the field they were seen in thick clumps, the clumps consisting of from 30 to 40 flagellate bodies. In these clumps were seen all the stages from a simple Leishman-Donovan body to a fully developed trypanosoma-like body. Several dividing ones were also seen possessing two flagella, two macronuclei, and two elongated bodies lying parallel to each other but possessing a single micronucleus situated transversely to the body. Several bodies were found which were indistinguishable from an ordinary Leishman-Donovan body except by the possession of a long flagellum. Besides these there were the fully developed ones, in which the body was elongated (much longer than a Leishman-Donovan body) and narrow and provided with a long thick flagellum. The flagellum was longer than the body of the parasite and was thicker than the flagellum of an ordinary trypanosoma (trypanosoma Brucei or Evansi). It took its origin from the micronucleus situated at one end of the parasite; in many the micronucleus was connected to the flagellum by a portion of darkly stained protoplasm. A vacuole-like organ was seen near the micronucleus; in some it was found towards the middle of the body of the parasite. The macronucleus was found situated in the middle of the body and was elongated in shape and not so defined as in the Leishman-Donovan body. No undulating membrane could be made out. The body of the parasite was filled with bluish-stained granules. No other structure could be made out. The posterior end (that opposite to the flagellum end) was finely drawn out as it were into a small flagellum.

In the moist hanging-drop preparation made on the third day the appearance of the fully developed parasite was most interesting. In examining the specimen under $\frac{1}{12}$th inch oil immersion lens I found several elongated flagellate bodies moving slowly across the field by a lashing side-to-side movement of the flagellum, this end being the front of the moving parasite. The movement was distinctly slow, much slower than that of an ordinary trypanosoma (trypanosoma Brucei or Evansi). No wriggling movement could be made out. The thick flagellum end was distinctly seen moving among the broken-down red corpuscles which were pushed out by the jerking movement of the flagellum. In one field I found a group of these parasites lying in a clump, their anterior ends being free, reminding one of the rosette formation of trypanosoma Lewisi by Laveran and Mesnil.[2] The free ends showed the movement of the flagella. In the free ones no movement in the posterior end of the parasite was seen.

The following peculiarities are noticeable in the parasites described above: (1) the position of the micronucleus at the anterior end of the body of the parasites; (2) the long, thick anterior flagellum; (3) the absence of (or, if present, rudimentary) undulating membrane; and (4) the rudimentary posterior flagellum. On account of the presence of these characters they would appear to be less closely allied to the class trypanosomidæ, such as trypanosoma Brucei and trypanosoma Evansi, than to the class of trypanopis described by Keysselitz,[3] which is characterised by the possession of a micronucleus at the anterior end, a long thick anterior flagellum taking its origin from the micronucleus, a rudimentary, undulating membrane, and a hardly discernible posterior flagellum which takes no part in the movement of the parasite.

In conclusion. I beg to express my indebtedness to Captain Rogers, officiating professor of pathology, Medical College, Calcutta, for kindly allowing me to publish the paper and for revising it.

DESCRIPTION OF THE PLATES.

Plate 1 is drawn from a comparatively crowded field showing numerous developed Leishman-Donovan bodies on the third day stained with Leishman's stain. Drawn under a $\frac{1}{12}$th inch oil immersion lens. No fully developed body is seen here; several dividing flagellated parasites as well as several elongated Leishman-Donovan bodies without any flagella are seen.

Plate 2.—From the same specimen, selected from several fields. No. 3 is a fully developed parasite curled upon itself.

Calcutta.

CHILD STUDY AND THE TREATMENT OF PARALYSIS IN CHILDREN.

BY ALFRED A. MUMFORD, M.D. LOND., M.R.C.S. ENG.
HONORARY PHYSICIAN TO THE GREENGATE DISPENSARY, SALFORD.

THE art of walking and of standing as carried on by a fully-developed human being seems at first sight to be hardly more difficult of acquisition than the swinging of a jointed pendulum. On more careful examination, however, each stage of movement and each position of rest are found to be gained only as the result of many trials and not a few failures, which have placed a complex arrangement of many muscles under the control of the will. It is difficult to overestimate the fact that each additional accomplishment is only acquired after much individual effort of the child and is not the mere exercise of an inherited nervous organisation. The intricate nature of the muscular arrangement is clearly brought out when by a partial paralysis of the limb some constituent element is thrown out of action. Defective or discordant movements then result. A similar complexity is noticeable in the movements of the upper as of the lower limb. This is evidenced by the fact that in extension of the hand on the forearm we not only contract the extensors but almost, though not quite, simultaneously we also contract the flexors of the wrist with a little less vigour. By this means we provide not only a break which

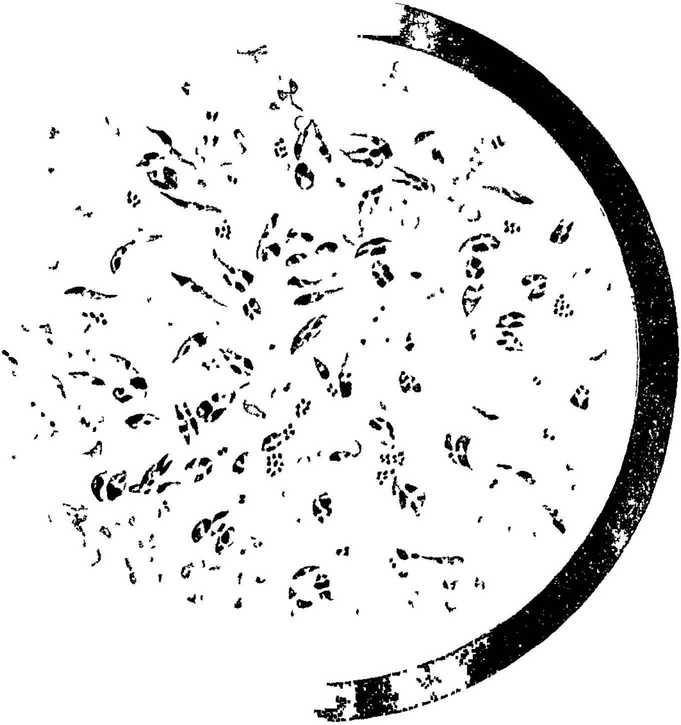

PLATE II

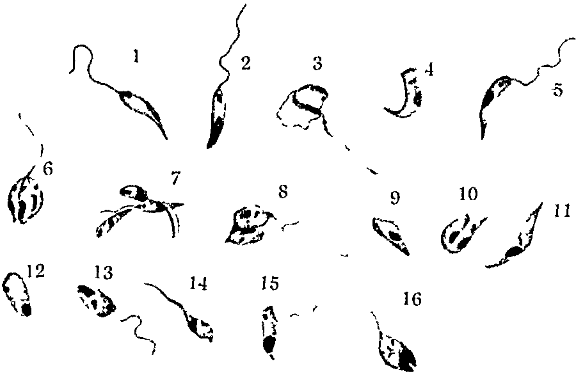


TO ILLUSTRATE DR. CHATTERJEE'S AND CAPTAIN ROGERS'S PAPER ON CULTIVATION OF TRYPANOSOMA OUT OF THE LEISHMAN-DONOVAN BODY.

prevents a jolt or excessive action but we also guide the resulting movements into a more precise and definite channel.

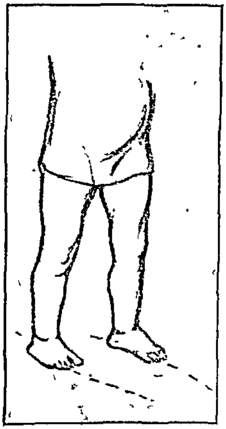
There are a considerable number of cripple children suffering from congenital spastic paraplegia who show in a very marked degree an *irregular or abnormal innervation* which is very instructive in any analysis of the movements of the limbs. The difference that should normally exist between the innervation of the *antagonistic groups* by which the predominant group receives more and the coöperating group less than its share of volitional impulses is well marked in these cases. This latter coöperating group, though it is insufficiently innervated, is not usually completely paralysed. The result of this as regards the legs is that spasm occurs in the predominating group such as the adductors and internal rotators, and paralysis of the abductors and external rotators. A more or less complete inability to use the limb naturally results. The cause of this disarrangement of innervation is generally that some portion of the cortex of the brain, or some portion immediately subjacent to the cortex, has been injured by disease generally before birth. From this cause the normal impulses do not arise from the cortex to set the limbs in action. To this must be added the fact that peripheral impulses of muscular and tactile sense also fail to reach the cortex and help in the elaboration by which the irregular and aimless movements of infancy become organised into orderly purposive movements. When the original disease has ceased to be active more or less recuperation of tissue occurs. The less injured areas become capable of discharging impulses and of receiving peripheral sense impressions. In cases of spastic paraplegia both these occur later than in the healthy child. There is in them a long period of listlessness, apathy, and paralysis. The children also generally suffer from defective speech. Mental deficiency is also common. Such cerebral impulses as do occur are irregular and unequally distributed to the different muscle groups, consequently the combined spasm and paresis already referred to result. If by the time the child is six or eight years old he has, of himself, acquired sufficient muscular coördination to be able to get about on crutches, orthopædic surgery is able to deal with the case and provide a more or less satisfactory limb In the severer forms of this *disease little or no benefit accrues from such* treatment. The extent of the spontaneous cure depends partly on the amount of brain tissue still left uninjured; it also depends largely on the means that are taken to ameliorate [illegible] child's attendants Further [illegible] will, I believe, enable us to [illegible] than has hitherto been [illegible] h effort made by the child, [illegible] effort, in achieving a new organised movement becomes in its turn a very potent therapeutic agent.

A number of cases of infantile spastic paraplegia were taken into the Greengate Dispensary about six months ago. They were apparently hopeless cases. A course of exercise-treatment was planned upon lines to be presently described. So much benefit has already accrued that it seems advisable to bring forward the methods adopted for the examination and criticism of those who have to deal with similar problems. These methods are based on a study of the natural order in which the normal child acquires control of the muscles used in walking and in standing. A brief description of the order of this development is therefore perhaps not out of place.

The movements of a very young infant largely consist of those of the head and neck, the eyes, and the coarser movements of the arm and leg. The order and degree in which these pass from spontaneous aimless movements into voluntary purposive movements have already been described by me in *Brain* (autumn number, 1897). At the age of three or four months normal infants have sufficiently acquired voluntary power over the spinal and other muscles to be able to sit upright and to look about them. An important part of their education in coördination has been obtained by kicking against the bed, &c., and so arousing the muscular and tactile senses; by this means they gain a knowledge of the force to be exerted *and* also a knowledge of position; by the sixth month the child exhibits sufficient pleasure in organised muscular action to enjoy pushing his feet against the floor when the attendant holds the body and allows the feet to dangle; and by the ninth or tenth month rhythmic movements of extension and flexion take place in the two legs alternately. These early movements, which are precursory to walking, seem to be partially reflex in character. Though the child cannot actually walk or stand he has already gained considerable control over the movements by which he will presently be able to do so.

Another element in standing—viz , balancing of the head and trunk—is next acquired. At first the child calls to his aid the hands and arms and balances himself by grasping his *mother's dress or some other object. This is half way to* bi-pedal progression. The position of the feet at this stage of learning is very characteristic. The legs are separated and widely apart, the toes are turned inwards, and there is a vigorous flexion of the great toe and the digits so that the feet seem to be actually gripping the floor. This stage is generally acquired by the twelfth month. (Fig. 1.)

FIG. 1.



[illegible] the important part played [illegible] are so tightly flexed that [illegible] loor. The toes are directed [illegible]

Before the child acquires the power of maintaining an erect position and of walking upright there is very frequently an intermediate stage of progression on all fours (Fig. 2).

FIG. 2.

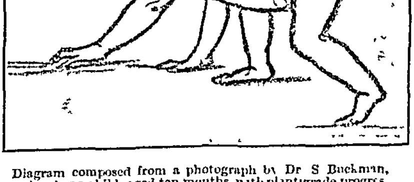


Diagram composed from a photograph by Dr S Buckman, showing a child, aged ten months, with plantigrade progression Transactions of the Cotteswold Naturalists' Field Club, December, 1899

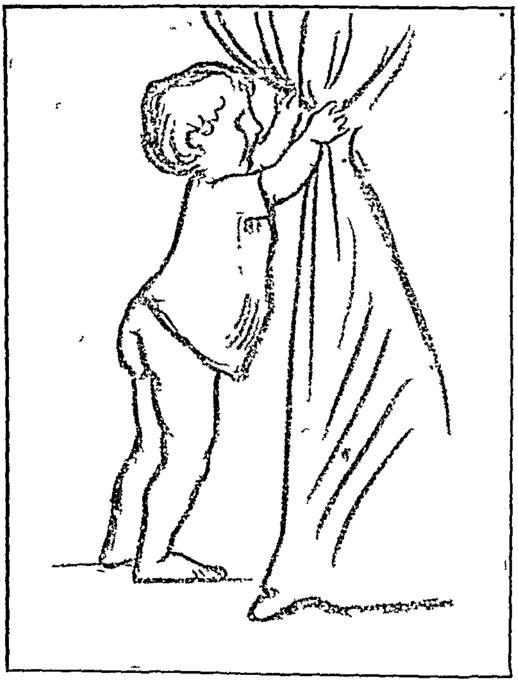
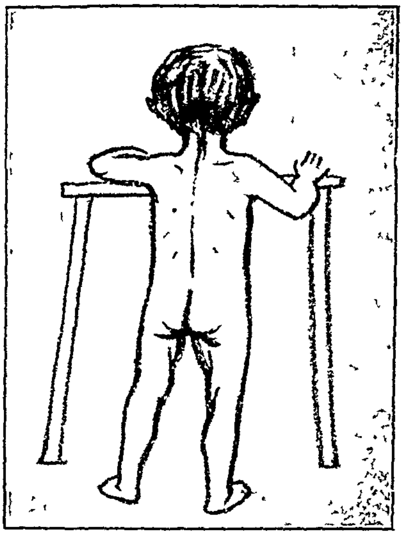
This is generally carried on by the child balancing his body on two hands and one foot, using the knee of the remaining leg as a paddle to push himself along. The everted position of the hands and soles of the feet exhibited in these movements of progression may be described as displacement ones. The movements were apparently originally adapted for a fluid medium but when used by the child against a rigid resisting medium such as the floor they result in moving the body of the child. Progression on all fours causes a great improvement in the muscles of the trunk. It also develops the abductors and external rotators of the thigh and helps to coördinate these with the adductors and internal rotators. The importance of understanding this stage is very great when we come to study the symptoms of spastic paraplegia of infancy. It is owing to the weakness of the external rotators and the abductors of the thigh that spasm occurs in the adductors and internal rotators when the child attempts to walk. The confusion causes the legs to become useless for walking or standing. The duration of the period of four-footed progression in the normal child is much influenced by the methods adopted in his early training. It is frequently entirely passed over.

FIG. 3.



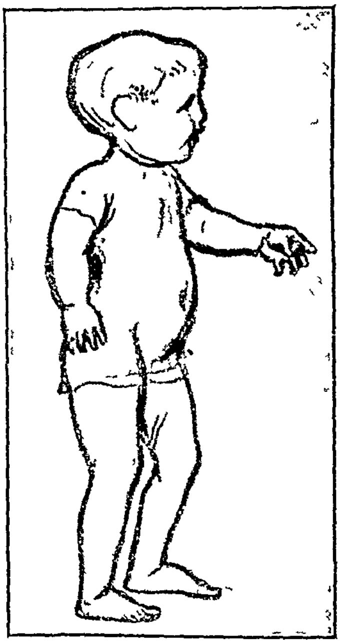
A normal child, about 20 months old, helping to raise himself by means of a curtain, he is able to use his legs when assisted by his arms

FIG. 4.



A normal child, 22 months old, able to stand on his feet when the arms and shoulders cooperate in supporting him.

FIG. 5.



A normal child, 22 months old, able to stand alone with the feet separated and the knees not quite extended, the arms are held out to assist balance

One observer records that his daughter who was entirely left to her own devices began to creep about on all fours by the end of the fifth month; by the end of the tenth month she moved briskly about on all fours like a monkey. She made no attempt at this time to raise the body into an erect position. Another observer writing in *Nature*, July, 1900, gave a photograph of a child, aged ten months, who also showed this four-footed progression very completely. After a febrile illness occurring a little later this power became completely lost. The method which a child naturally follows in acquiring control over his limb movements has suggested the line adopted in the treatment of the cripples at Greengate Dispensary. The teacher or masseur began by steadily practising flexion and extension of the almost useless legs. After a time he practised a slow external rotation and circumduction of both thighs. He constantly massaged all the muscles to stimulate them to healthy action and to overcome the rigidity. These exercises were practised for a few minutes at a time at least 12 or 14 times a day. The child's attention was constantly directed to these movements that they might be permanently engraved on his memory and so become organised in the cerebral cortex. Presently an attempt was made by the child when lying on his back to make these movements voluntarily and without the accompanying spasm. As soon, however, as the child was held upright and the legs were allowed to dangle the spasm returned on the child making any exertion. Spasm was always held to be a reason for stopping the treatment temporarily. Spasm also occurred on any excitement. The next stage consisted in an attempt to imitate the four-footed method of progression. The child was laid on his face, a bar fixed to a chain was placed in his hands, and while lying face downwards he was encouraged to pull himself forward. The mere lying in this position is good, for it produces extension of the hips together with some abduction. Voluntary exercise in this position leads almost automatically to a certain amount of external rotation and a separation of the thighs. In the early stages the legs themselves hardly seem to participate at all in the forward movement but remain inert; presently, however, they definitely do participate and a step forwards to quadrupedal progression is secured. About this time the child can be taught voluntary movements of abduction and circumduction of the thighs and also alternate flexion of the two legs. When by means of these movements a fair degree of flexibility and a diminution of the spasm have been secured a further stage may be tried and the child encouraged to put his feet upon the floor. Like an infant, his body must at first be securely held. Then again following the lines of normal progress the child may be encouraged to balance himself by holding on to the side of the bed or a suitably constructed walking frame.

Attention has now to be paid to the movements of the shoulders and the arms. Reference to Figs. 3 and 4 shows that in normal children the muscles of the shoulders and the arms play a very considerable part in maintaining the balance of the body at this stage. In the case of the cripple children these muscles, like those of the leg, are very weak and ill-developed. They need special attention. Accordingly parallel bars are arranged of such a height that when the child is held upright, with his arms held straight downwards, he can just grasp the bars while his feet touch the ground. He then learns to hold himself from the shoulder.

When by these means a fair degree of balance has been gained the child may be trained to use crutches. Volitional control over the coarser movements of the thighs and knees has been gained but without the power of grasp in the hands and the power of holding the arms and shoulders rigid; this has been found to be useless. Whether further power can also be gained in the finer movements of the ankle and foot must be decided by further experiments. It may be that methods of orthopædic surgery will alone be efficacious—the children at Greengate Dispensary are under the supervision of surgeons who have interested themselves in this branch of work. Sufficient experience has been gained to justify the workers at the Greengate Dispensary in the prosecution of further researches. It is hoped that others who have thought much upon this matter will offer suggestions or criticisms.

It may be added that these movements and exercises are evidently a source of real pleasure and joy to the child and that he increases in weight, in vigour, and in mental alertness while they are being continued. Constant intermission must be provided as he very readily tires.

Manchester.

DIET IN CHRONIC DISEASES.

BY JOHN HADDON, M.A., M.D. EDIN.

As the subject of diet is receiving considerable attention, more especially in America, the following cases seem worthy of being recorded.

CASE 1.—The patient, an unmarried woman, aged 66 years, had an illness when 18 years old which was said to be a gastric trouble and at that time she was ill for two years. She had had similar attacks every seven years since and had been more or less an invalid. When seen in consultation with her medical attendant on June 28th, 1904, I found that she had been in bed for six months and was being fed on Benger's food, having one grain of morphine in a suppository every night, and was reduced to a perfect skeleton. She brought up, apparently by a kind of eructation, fluid of a greenish colour, varying from half a pint to a pint during the day. The bowels did not act except by medicine or an enema. She was taking food to relieve pain which came on two hours after food and which the food relieved. She was supposed to be dying and looked as if she were. The skin over the left side of the abdomen and the ribs was very sensitive to touch. There was no distension but some dulness on both sides, due probably to fæcal matter, and fæces could be felt in the intestines. There were splashing in the stomach and abdominal pulsation. The pulse was weak and the heart sounds were feeble, without any murmur. She was too weak even to sit up. She was ordered to have nothing except water. On the 29th, about 2 A.M., her sisters, who were nursing her, thought that she was dying and sent for her medical attendant who ordered an enema of beef-tea and brandy in teaspoonfuls by the mouth. When I saw her in the forenoon she had brought up three-quarters of a breakfast-cupful of the greenish fluid since the day before and had drunk six breakfast-cupfuls of water, mostly on the previous day. She had a natural motion in the morning, with traces of yellow, that which the enema had brought away before being of a dark colour throughout. The dulness on the right side of the abdomen had disappeared and there was no splashing in the stomach. She cried out with pain in the epigastrium, but there was no tenderness on pressure and the pain was intermittent, not lasting long. She had slept four hours in the night. Tracing No. 1 shows the character of the pulse and was the best that could be got. She was ordered to have five figs boiled and the soup from them given in tablespoonfuls every four hours, with water if she wished during the intervals. On the 30th she did not sleep but the pain was less severe. She had had three pints of water and had vomited two pints of the greenish fluid, darker than before, which was coloured no doubt by the fig soup. She was more cheerful and hopeful. Something like an enlarged appendix could be felt in the right side of the abdomen. There was no flatulence. The urine was normal. She was ordered to have five figs stewed, the juice to be concentrated to a teacupful and given every four hours.

On July 1st the patient said that she had not slept in the night but had lain and talked to herself, which surprised her. She had had a scanty yellow motion with some black pieces in it and had brought up very little fluid since the previous day. She said that she had pain after the fig juice but had vomited nothing since she had it at 8 o'clock in the morning. She was ordered to have ten prunes stewed and their juice, alternately with that of the figs, at intervals of four hours as before. Tracing No. 2 shows the pulse. On the 2nd she had slept for five hours in the night. The prune juice had caused her more discomfort than the fig juice. She looked much better and could sit up. There had been a motion in the morning which was thin and smelt badly. At noon she sucked the juice from some onions which had been cooked till they were sweet. She was ordered to have the prune and fig juice mixed and to take it alternately with the onions every four hours.

On July 3rd she had slept for three hours in the night. She was said to have been very bad at 2 A.M. and could not speak. Four ounces of whey were given at 1 P.M. and this was ordered to be continued every four hours with one date between. On the 4th there was no complaint of weakness in the night. There was no motion or flatus passed and fæces could be felt in the left side but no distension. Fulness was still felt about the region of the appendix. She was ordered to have eight ounces of whey every four hours and a date with it. She looked much better. On the 5th she had slept for four hours in the night and had had a motion which was hard and dark in colour. On the 6th she had slept for two hours in the night. There had been a copious motion at 6 A.M., the hard portions of which were still dark in colour, while the soft portions were yellow.

On July 7th she had a motion.

FIG. 1 (CASE 1).

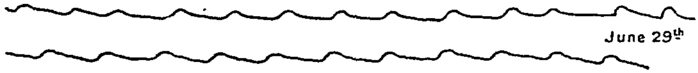


FIG. 2 (CASE 1).

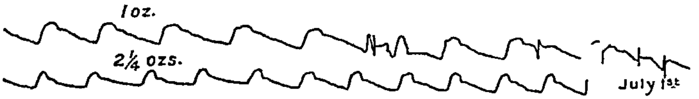

natural-looking and she had no complaints to make. She had eaten 18 dates since the day before without pain and had slept for five hours in the night. At noon half a teacupful of wheat-meal and malt pudding was given. The patient was up in the afternoon and walked into another room where she sat for an hour. From this date she continued to move about and to exercise herself in the house. On the 11th she weighed 4 stones 10 pounds 4 ounces, she being a tall woman On the 21st she went to the country and was walking about the road making good progress. Her nurse having left and her sisters having taken her in hand I left off attendance.

CASE 2.—The patient, a man, aged 29 years, had always been delicate. In January, 1904, his medical attendant said that he had Bright's disease. His legs were swollen and pitted on pressure. He had a cough but did not spit. He was able to get up a little while every day. There was some dulness on the right back and the respiratory sounds were better heard over the right than the left back. There was no dulness in front. He was fairly well nourished but the skin was pale. He took the usual food. The bowels sometimes were loose and at other times were confined. The urine looked turbid, frothed, and had a sweetish smell. He passed over two pints in 24 hours (specific gravity 1010) with one-fourth of albumin depositing when tested by nitric acid. He was not able to sleep well.

On June 17th he began to have only stewed rhubarb at 8 A.M. and 3 P.M. No. 1 tracing shows the pulse. On the 18th he said that he had slept better. On the 21st he said that he was having much better nights and was neither hungry nor thirsty on the rhubarb alone and he had now no cough whatever. On the 28th No. 2 tracing shows the pulse. There was much less swelling in the legs and he was sleeping well. Onions and grape nuts had been added to his dietary. The bowels acted regularly and there was only one-eighth of albumin in the urine. In spite of the improvement his mother would not continue the restricted diet and I did not see him again.

FIG. 1 (CASE 2).

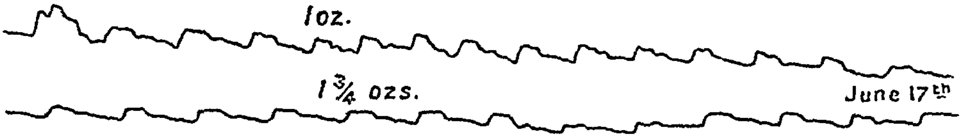

FIG. 2 (CASE 2).

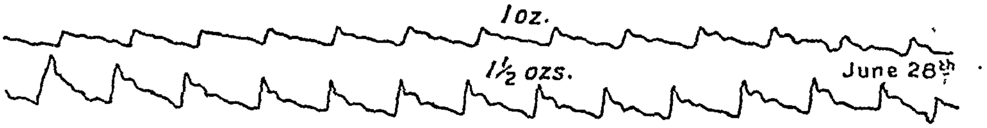

CASE 3.—The patient, a man, aged 41 years, was a neurasthenic who felt at times as though he would go mad. He had visited hydropathic establishments of different kinds without any permanent benefit. For many years he had suffered from repeated attacks of pain in the stomach and vomiting. His bowels had been generally constipated and had required either medicine or an enema to move them. Insomnia had been a prominent symptom. On Oct. 21st, 1904, being 5 feet 8½ inches in height, he weighed 8 stones 13 pounds 2 ounces in his clothes. His tongue had a thin white coat except round the edges. His tonsils were enlarged and there was a redness all over the back of the throat. His pulse was 52, with considerable tension. The heart sounds were normal. Fæces were felt in the left side of the abdomen. There was no distension, the clearest note being on the right side. He was depressed mentally and physically but was fairly well nourished, his ribs being well covered. A hymn would come into his head which he could not get rid of and he would get into a state of what he called "mental excitation" and wished to be alone. He had noises in his ears like a cataract, with a whistle at times. He was ordered to have half a teaspoonful of China tea infused in a pint of water for ten minutes at 9 A.M. and to have nothing except water at other times, taking as little as possible except at 6 A.M., when he was to drink a pint in bed. On the 22nd he had slept from 11 P.M. till 2 A.M. He felt stupid when he awoke and his eyes were sore, as though they would drop out, and he could not bear the light. He had pain after drinking the water at 6 A.M. and some mouthfuls of frothy bitter fluid came back. He passed no urine till rising at 7 A.M. and then 130 cubic centimetres of a high colour and of specific gravity 1030. Acute pain was felt after taking the tea at 9 A.M. and there was some giddiness. He worked in the garden during the day at weeding. His head felt queer and he was giddy. Some frothy stuff came up after drinking water. Flatus passed at night. During the day 130 cubic centimetres of urine were passed, of specific gravity 1030, and it deposited about one quarter of urates. He thought that he had retained over half a pint of water since he had the tea. On the 23rd he had slept from 11 P.M. till 2 A.M. He had been dreaming a great deal. There was less depression than on the previous morning and he was a bit stiff in the legs from working in the garden. The tongue was furred and had not the smooth coat which it previously had. The amount of urine passed in the night was 620 cubic centimetres; it was clear, with a specific gravity of 1010. Bitter fluid still came up and he felt full, as he always did, in the epigastrium. He walked for three hours, climbing a high hill. The physical depression was less at the top of the hill than when he started. He again walked from 7 P.M. to 9 P.M. and felt a bit tired. He said that he had had less depression, both physical and mental, than usual and that in the evening his mouth was watering and had no bitter taste in it and he felt as if a crust of bread would taste good. The amount of urine passed during the day was 360 cubic centimetres, of specific gravity 1020, and clear. His weight was 8 stones 10 pounds 12 ounces

On Oct. 24th he had slept from 11.30 P.M. till nearly 6 A.M. There was no pain after taking the water in the morning and very little returned. The urine passed in the night amounted to 365 cubic centimetres and was of specifi gravity 1014. He refused to take the tea and on wishing t know his reason he said that it was a stimulant, that i removed the mental depression, and he was determined t take nothing in the shape of drugs. He took the hot wate alone. He had more distension in the stomach from wate alone than from the tea. The tongue now was not furre and looked cleaner than at first. He worked in the garde all day. At night he felt fairly well. Nothing returne when he drank. The urine passed during the day amounte to 1250 cubic centimetres, with a specific gravity of 1005 His weight was 8 stones 9 pounds 14 ounces. The bowel were moved by enema; the fæces were dark and fou smelling but not hard. On the 25th he had slept well i the night till nearly 7 A.M.; during the night he ha passed 900 cubic centimetres of urine, of specific gravit 1004. His weight was 8 stones 7 pounds 6 ounces. Ther were little, if any, mental depression and no feeling o physical depression. He left to visit some relatives, sayin that he would be careful as to food.

I make no comment on such cases but put the facts befor the profession, hoping that they may tend to the study o diet, not only in such cases but in all diseases, and tha other facts may be accumulated for future guidance.

Denholm, N.B.

HOSPITAL SATURDAY IN TORQUAY.—As a resul of the recent Hospital Saturday collections in Torquay th sum of £195 was handed to the authorities of the Torba Hospital. This is the largest amount which has ever bee received for this fund in Torquay.

CORNWALL COUNTY NURSING ASSOCIATION.—In response to the appeal of Lord Mount Edgcumbe on behalf of the funds of the Cornwall County Nursing Association the sum of £184 has been promised annually in subscriptions, leaving an additional income of £100 which is stil required to place the association on a sound financial basis.

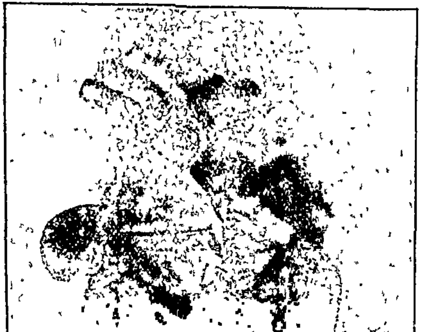
NOTE ON A CASE OF DOUBLE STENOSIS OF THE AORTIC ORIFICE.

By THEODORE SHENNAN, M.D. EDIN., F.R.C.S. EDIN.,
PATHOLOGIST TO THE ROYAL INFIRMARY, EDINBURGH, ETC.

THE case of double stenosis of the aortic orifice published in THE LANCET recently,[1] brings to my mind an analogous case which Dr. H. G. Langwill and I described with an illustration in the *Scottish Medical and Surgical Journal.*[2] It is referred to at some length by Clifford Allbutt as a "subvalvular constriction" in his article on Diseases of the Aortic Area of the Heart in his "System of Medicine."[3]

The main points of the case are as follows. The patient was a male, aged 19 years. There was no history of rheumatism or scarlet fever. He was poorly developed and pale; there was no œdema or cyanosis; marked clubbing of the fingers was present. As regards the circulatory system there were marked episternal pulsation, a marked systolic thrill to the right of the middle line in the first and second intercostal spaces, and a "blowing" systolic murmur in the mitral area, becoming louder on auscultating up the sternum to the aortic area, so as to become audible five inches from the chest wall. The patient died suddenly.

Necropsy.—This was *performed hurriedly, the heart only* being removed and sent to me for examination. Nothing of importance was found in the auricles or right ventricle The walls of the left ventricle were hypertrophied Some of the columnæ were fibrous, evidently from old endocarditis On passing the finger up towards the aorta it passed through a fibrous ring—0·7 inch in diameter—about one inch below the aortic opening. This was continued on to the ventricular surface of the inner mitral cusp. In this position and extending upwards from the ring on to the lower surface of the left posterior aortic cusp was a narrow band of comparatively recent vegetations These covered the lower surfaces of all the aortic cusps, which also were thickened and contracted, the diameter of the opening being 0·7 inch. The aorta was dilated slightly at its commencement but in the upper part of the descending aorta was only 0·6 inch in diameter. The fibrous ring was apparently the result of an old endocarditis.



A portion of the wall of the left ventricle is removed and the aorta laid open The fibrous ring is indicated by the pointer. Just above it are the thickened aortic cusps.

The condition is well seen in the accompanying illustration. The specimen now forms specimen No. 89 of Series 36 in the Museum of the Royal College of Surgeons of Edinburgh and is fully described in the Catalogue, Vol. III.

Edinburgh.

A NOTE ON THE OCCURRENCE OF FILARIA IN FIJIANS.

BY G. W. A. LYNCH, M B, B C. CANTAB., M.R.C.S. ENG., L R C P LOND.,
RESIDENT MEDICAL SUPERINTENDENT, COLONIAL HOSPITAL, SUVA, FIJI.

DURING a period extending over 13 months the blood of 608 pure Fijian natives was examined at the Colonial Hospital. In every case specimens of the blood were taken both by day and by night and examined shortly after they were prepared. The natives whose blood was examined were from every part of this group of islands and really comprised all the Fijians who were admitted to hospital during the period of observation—adults and children, males and females; but adult males form the majority, because there are always fewer females and children in the hospital admission lists. Of the 608 cases examined filaria embryos were present in 156, or 25 65 per cent. In 125 specimens of blood taken by day and 136 specimens taken by night embryos were present, and 105 cases showed them in both day and night specimens; so that 31 cases showed filaria in their night specimens only and 20 cases in their day specimens only, or 5 09 per cent and 3·28 per cent. respectively. The embryos examined were similar to those of filaria nocturna in all cases but one, and though in some cases it could be said that where found in both night and day specimens the embryos were in increased numbers in the former, this was by no means always so; indeed, in some the very opposite conditions prevailed and it was frequently noted that the number of embryos was about equal in the blood examined by day or night. The one exception noted was that of a female patient from the province of Lau in the Windward part of the group, whose blood showed undoubted embryos of filaria perstans; this was found on all the occasions on which her blood was examined. These patients were, of course, admitted to hospital for all kinds of disease; but some were admitted for the acute febrile attacks which are of common occurrence in Fijians who are filarial; there were 16 of these in all. These attacks of "fever" are so common amongst the natives that they are not as a rule in the habit of seeking hospital assistance for this complaint. 15 cases were admitted for abscesses of various parts of the body which had [illegible] filarial [illegible] the [illegible] roin were admitted in the period under notice, which were also of filarial origin and showed embryos in the blood. (In this connexion it may be noted that of course no account is taken of the large numbers of ordinary abscesses or inflamed glands due to other ascertained causes.) During the period of observation 13 cases of advanced elephantoid enlargements either of the scrotum or other parts of the body were admitted; of these 11 showed no embryos in their blood but two showed them without any doubt whatever. In all 119 females were examined; 21 cases showed embryos in both night and day specimens and four in night specimens only; 489 males were examined, so that 21 per cent. of women were infected and 26·78 per cent of men; the difference may be accounted for by the much smaller number of women examined. Only eight cases of children under 13 or 14 years of age were examined and these in no instance showed any sign of disease.

[1] THE LANCET, Nov. 19th, 1904, p 1417.
[2] Scottish Medical and Surgical Journal, vol. i., 1897, p. 723.
[3] Allbutt's System of Medicine, vol. v., p. 919.

The accompanying table shows the various provinces of Fiji from which these cases came.

Province.	No. of cases examined.	Cases in which filariæ were found.	Percentage.	Remarks.
Rewa	46	9	19·56	River delta.
Tailevu	60	19	31·66	Coast and high land.
Ra	20	4	20·00	Ditto.
Ba	16	4	25·00	Ditto.
Nadroga	20	6	30·00	Ditto.
Serua...	25	3	12·00	Ditto.
Naitasiri	12	1	8·33	Inland.
Colo East, West and North ...	26	8	30·76	Mainly high land.
Cakaudrove ...	34	8	23·52	Mainly island and coast.
Lomaiviti... ..	107	22	20·56	Island archipelago.
Bua	31	16	51·61	Coast and high land.
Macuata	14	3	21·42	Coast and high land.
Lau	105	24	22·85	Archipelago.
Kadavu	76	27	35·52	Island.
Namosi	5	0	—	Mainly high land.
Unspecified ...	11	2	18·18	—
Total ...	608	156	25·65	—

Making due allowance for differences in the numbers from the various provinces, it appears that the prevalence of this disease is about equally great in all parts of the group; it does not seem possible from the table to say that it is found more in the coast provinces than those inland. As a matter of experience, however, most of those patients who come from essentially inland provinces live in those parts of such provinces which have a fringe of sea coast.

Colonial Hospital, Suva, Fiji.

A NOTE ON A CASE OF BILHARZIAL WORMS IN THE PULMONARY BLOOD IN A CASE OF BILHARZIAL COLITIS.

By WILLIAM ST. CLAIR SYMMERS, M.B., C.M. ABERD.,
PROFESSOR OF PATHOLOGY AND BACTERIOLOGY, THE EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE; PATHOLOGIST TO THE KASR-EL-AINI HOSPITAL, CAIRO.

THE following facts are, I think, worthy of publication for two reasons: first, bilharzia hæmatobia has never before been seen in the blood of the lungs; and, secondly, the condition here named "bilharzial colitis" is not sufficiently recognised as a cause or concomitant of certain "dysenteric" symptoms.

The patient was a male Egyptian of uncertain age, probably about 35 years old. Clinically the disease was diagnosed as dysentery as all the symptoms pointed unmistakeably (as was thought) to this condition. But the post-mortem examination revealed a totally different state of affairs. The small bowel was normal except for the presence of about 100 ankylostomata. The colon and rectum were pale pink, the mucous membrane was swollen and velvety with a very few superficial abrasions, but universally raw in appearance and covered with a fair amount of mucus. The wall of the large bowel was somewhat thickened and its muscular coat was œdematous and hyaline in appearance. There were none of the ulcers characteristic of dysentery. Very numerous bilharzial ova were present in the mucous membrane of both the colon and the rectum. It seems most probable that the marked dysenteric symptoms in this case were due to the irritation of the innumerable bilharzial ova which were present in the mucosa of the gut.

As to the presence of the bilharzial worms in the body the facts were as follows. 22 worms (males) were found in the portal blood but the most interesting point is that two worms, a male and a female in the act of copulation, were found in the blood of the left lung. Ova of bilharzia have been recorded[1] in the tissue of the lung, but, so far as I am aware, no one has hitherto seen the living worms in the pulmonary circulation. I do not care to speculate as to how these worms got to the lung but I venture to refer to the fact that bilharzial worms are often found in the veins around the urinary bladder and in the small vessels about the rectum and that the blood from the whole vesical plexus of veins and part of that from the hæmorrhoidal plexus are poured *viâ* the internal iliac vein into the *systemic* circulation, so that a worm coming from either of these situations would have open to it a direct channel through the right heart to the lungs.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Prooemium.

EVELINA HOSPITAL FOR SICK CHILDREN.

A CASE OF CONGENITAL STENOSIS OF THE LOWER END OF THE ŒSOPHAGUS; WITH REMARKS.

(Under the care of Dr. T. R. C. WHIPHAM and Mr. C. H. FAGGE.)

A LITTLE girl, aged four and a half years, was taken to the Evelina Hospital as a medical out-patient on August 7th, 1903. Her mother was in an asylum and, as her father could not look after her, the child had been handed over to the care of a woman "whose lodger knew the child's family." The history given by this woman was that the child had vomited immediately after food for at least three and a half years and was believed to have done so all her life. The vomiting occurred after nearly every meal with occasional intervals of one or two days. There was never any difficulty in swallowing but the food was rejected as a rule within a very short time of being ingested. If the vomiting did not occur almost immediately the food was invariably retained. No difference was noticed between fluids and solids, though it was observed that the latter, if not properly masticated, were generally returned. Milk and biscuits were said to be sometimes retained and sometimes rejected, but on the whole porridge was kept down best of all. The bowels acted regularly. There had never at any time been hæmatemesis or any symptoms pointing to a cerebral lesion. The child herself had had only measles two years previously and there were five other healthy children in the family.

When first seen the patient had a somewhat pallid aspect and was much emaciated, the eyes being sunken and surrounded by dark rings. Her weight was only 15 pounds 12 ounces. The tongue was covered with a slight brown fur. The abdomen was flat and fæcal masses were felt in the descending colon, but nothing abnormal could be found. Examination of the chest likewise gave no abnormal signs. She was ordered cod-liver oil and malt, compound liquorice powder, and ten-grain doses of the subnitrate of bismuth. No improvement followed. Vomiting occurred as a rule after the medicine and every few mouthfuls of food, though occasionally milk, &c., were retained, with the result that at the end of a week the child had lost six ounces in weight. The treatment was continued and an improvement followed, porridge being kept down well twice a day and the medicine retained. Thus at the end of the second week the weight had increased to 19 pounds 7 ounces. The improvement however was only temporary, for the child again began to lose ground. The vomiting became more marked and, though the oil and malt were fairly well retained, at the end of the next six weeks she turned the scale at only 17 pounds 8 ounces. The bowels continued to act regularly. The history of the vomiting was confirmed by feeding the child with milk and bread and butter in the out-patient room She ate and drank readily and swallowed without difficulty, but generally after taking three or four mouthfuls she would stop and say she was going to be sick without apparently having any feeling of nausea A "pumping" action like that seen in dogs, then began and after a few seconds the food returned undiluted except by saliva and without any acid reaction At times after a drink of milk or a coloured solution had been retained she was given some bread and butter, which was immediately returned without any of the previous fluid thus proving that the solid [illegible] After vomiting the child

discomfor

at this ti

case mig

The frequent demonstration of the vomiting however, put the latter out of cour

By the courtesy of Dr W Soltau Fenwick a bed in the hospital was obtained for the child and she was taken in on Oct 14th after nine weeks out patient treatment and watched by Dr Whipham She was given a full diet with such extras as cream Brand's essence and ginger bread nuts The appetite was good and the child retained fluid food well but, with only occasional exceptions was sick after her solid meals though curiously the ginger bread of which she was very fond was invariably retained Various changes in the nature and quantity of the food administered were tried, but the result was always the same and at the end of a month after admission her weight had only increased by four ounces Nutrient enemata in addition to oral feeding were tried for a time but had to be discontinued after a fortnight on account of intolerance of the rectum During this time however, the weight had gone up to 18 pounds 12 ounces The child's general health continued satisfactory the only drug exhibited being liquorice powder for the relief of constipation

Examination under anæsthetics by means of bougies and the x rays on different occasions led to a modification of the diagnosis of œsophageal pouch The passage of a moderate sized bougie was arrested at the lower end of the œsophagus while a No 2 or 3 catheter passed readily into the stomach Experiments with the x rays on catheters containing soft wire confirmed this fact for the smaller tubes were seen to enter the stomach while the larger ones were arrested about two inches above the diaphragm One soft catheter threaded with very flexible annealed wire was found to be reflected at this point and that a considerable dilatation of the œsophagus above existed was shown by the distance between the descending and ascending portions of the catheter That the condition was not one of a diverticulum seemed now evident The vomiting came on immediately after meals and not after an interval and there was no dysphagia, moreover there was never any swelling in the neck which is the constant position of congenital œsophageal pouches their site being at the end of the pharynx A traction pouch due to adhesions to an inflamed mediastinal gland seemed also out of the question for these as a rule are small and cause no symptoms Above all the passing of the œsophageal tubes pointed to a true stricture, for the smaller invariably entered the stomach, while the large were stopped as described above A diagnosis of that rare condition congenital stenosis of the lower end of the œsophagus was consequently made and this as subsequent events proved was the correct one

As the child had made no real progress with careful dieting during her six weeks stay in the hospital a consultation was held towards the end of November as to the advisability of surgical interference so on Nov 23rd with the patient under chloroform and aided by the x rays Mr Lagge passed gum elastic catheters containing fine wire stylets (sizes 2 and 3) through the stricture Larger sizes without stylets were tried without the use of force but could not be guided through the stricture though if softened by hot water they were seen to curl up above it

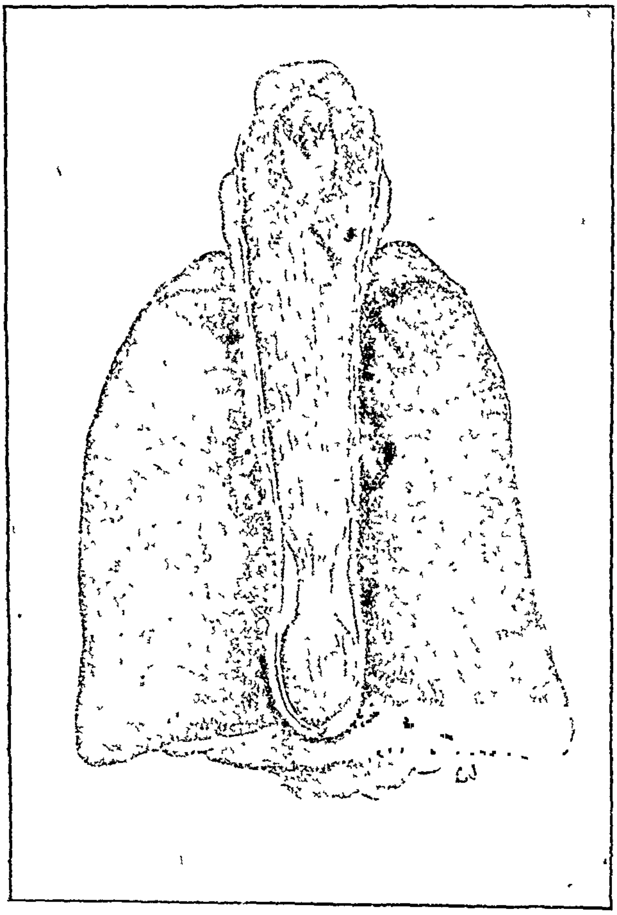
Messrs Down Bros were then instructed to make a series of gum elastic catheters of the usual sizes with centrally placed round terminal openings into which fitted the bulbous end of a fine wire This was passed through the catheter and was of such a length as to pass well beyond its upper end The object of this was that the smaller catheter might be withdrawn leaving the stylet *in situ* over which a larger sized catheter could then be passed through the stricture guided by the stylet

On Dec 4th the patient was again anæsthetised on the x ray couch and a very small Killian's œsophagoscope was passed but when this reached the pharynx it impinged on to the posterior wall at about the level of the fourth cervical vertebra, and as it was felt that it could not be passed further without undue force it was withdrawn A No 2 catheter, with a fine flexible wire stylet ending in a bulbous point as described above, was then passed with ease and was seen by the x ray screen to have passed into the stomach The catheter was then withdrawn, the wire stylet remaining *in situ*, and gradually larger catheters were passed over the stylet until a No 11 had been introduced The larger sizes were allowed to remain in the œsophagus for several minutes before being withdrawn so as to dilate and not merely to stretch the stricture During the passage of these instruments there was no sense of great obstruction which necessitated the use of force to push the catheters on, in fact only the largest size introduced was gripped at all and the greatest care and delicacy were exercised in their introduction Nor during their passage through the upper part of the œsophagus was there any sense of any resistance being overcome and followed by free movement of the end of the catheter, such as would have been caused by its escape into the cellular tissue outside the œsophagus Each catheter with its contained wire stylet was "screened while in the stomach and frequent observations were made with the screen in an attempt to determine the length of the stricture and the distance of its lower end from the cardiac orifice of the stomach

The patient was taken back to bed but on recovering from the anæsthetic swelling of the right side of the neck was noticed during the next two or three hours which spread steadily and rapidly to the left side and up on to the face The swollen parts crepitated under pressure and were somewhat painful when touched The child was very restless and the breathing became laboured By the next day the emphysema had spread over the thoracic and abdominal walls and the temperature began to rise respiration was more embarrassed, and the heart's action was rapid and weak The general condition was much worse and it was only too evident that during the attempts to dilate the stricture the œsophageal wall had been unfortunately perforated During the following two days (Dec 6th and 7th) the subcutaneous emphysema varied slightly in amount from time to time but delirium, cyanosis and intense abdominal pain which was only relieved by morphine, supervened Four Southey's tubes were inserted into the subcutaneous tissues of the neck and chest but failed to relieve the tension On the 7th the patient was very distressed and had much difficulty in swallowing She was continually retching and frequently vomited brown material Continued stimulation was of no avail and she died that afternoon with a temperature of 104 8° F Her weight taken three days before death was 19 pounds 12 ounces

Necropsy —At the post mortem examination the body was found to be fairly well nourished The subcutaneous tissues were much distended with emphysema which extended from the face over the thorax and abdomen the right side of the neck and face as high as the supra orbital ridge being the parts most affected The upper part of the œsophagus was dilated and at a point three quarters of an inch below the level of the bifurcation of the trachea there was a sudden narrowing of the calibre the tip of the finger just entering a circular ring which partially yielded to quite moderate pressure On slitting up the œsophagus the stricture was seen to be of a fibrous nature and quite half an inch in length (see illustration) In appearance it was white thick semi translucent and firm and quite unlike the remainder of the œsophageal wall which was such as is usually seen The stricture terminated one and one third inches above the cardiac orifice of the stomach and the lower end was as sharply defined as the upper The terminal portion of the œsophagus below the stricture was also somewhat dilated On the right side a little below the epiglottis there was a small perforation through all the coats leading into the surrounding loose cellular tissue One inch below this there was a small laceration of the mucous membrane and just above it were two symmetrical oval patches one on either side of the lumen where the mucous membrane had been slightly injured There was no evidence throughout the œsophagus of any old traumatism erosion or ulceration From the perforation a large septic track containing air and a small quantity of offensive grumous fluid, probably food, led down into the mediastinum which was also infected

The right pleura was the site of a large pneumothorax. It contained a few ounces of yellowish fluid and was covered by an adherent layer of lymph. No evidence of perforation of the pleura was found. The lung was collapsed and airless. On the left side there were numerous petechial hæmorrhages under the pleura which presented a little lymph and contained a small quantity of fluid. The left lung was normal. The pericardium contained a slight excess of fluid and loose shreds of lymph around the base of the heart. The heart itself was normal. The stomach showed advanced post-mortem digestion and tore easily. There was no peritonitis or lesion of the abdominal viscera beyond several small subperitoneal hæmorrhages over the surface of the liver. The condition of the œsophagus was the only abnormality present in the body.



Œsophagus laid open from behind, showing the position and extent of the stricture A rod is passed through the perforation. From a drawing by Mr. Lawrence Jones.

At the post-mortem examination it was considered that the bare bulbous-ended wire stylet had produced the hole which did not seem large enough to have admitted any of the catheters. Unless the same instrument had passed into the cellular tissue and wounded the pleura, the occurrence of the pyo-pneumothorax is not explained, but the pathologist (Dr. R. P. Rowland) could find no evidence of an injury to the parietal pleura near the hole in the œsophagus

Remarks by Dr. WHIPHAM and Mr. FAGGE.—Congenital malformations of the œsophagus of any kind are but seldom met with. Records of individual cases are found scattered over the literature but the text-books dismiss the condition in a few lines. Briefly speaking, these abnormalities may be devided into—

1. Congenital absence of the whole œsophagus—a very rare condition.[1]

2. Bifurcation of the œsophagus with junction of the two parts towards the lower end.[2] Of this condition we only know of one recorded instance.

3. Congenital atresia in which the œsophagus is divided into two parts—the least rare of all the varieties. As a rule, in these cases the upper end, which is continuous with the pharynx, ends blindly in a more or less expanded cul-de-sac, while the lower opens above into the trachea or one of the bronchi and below in a normal manner into the stomach. The two segments of the gullet may be connected by a fibrous or muscular band.[3] Much more rarely there is no opening of the lower part into the air passages, the two blind ends being merely joined by a fibrous cord.[4] In connexion with the upper cul-de-sac pressure pouches are sometimes formed. The obliteration of the œsophagus in such cases is stated to be a secondary process occurring opposite the diverticulum from which the lower part of the trachea and the lungs are developed.[5] It will be remembered that the epithelial lining of the larynx, the trachea, and all the air passages are derived from a diverticulum which arises immediately below the epiglottis from the ventral wall of the foregut.[6]

4. Pressure pouches which occur in the median line posteriorly are thought by some to be of congenital origin and to have become gradually dilated by the passage of hard food. That such exist during fœtal life is unlikely, especially as symptoms are not generally noticed till age is well advanced, or may be entirely wanting and the condition only discovered at the necropsy.

5. Stricture caused by a fold of mucous membrane projecting into the lumen of the tube, like a diaphragm (*a*) at the upper part of the œsophagus immediately below the pharynx or (*b*) near the lower end. The symptoms of such lesions are in most cases not manifested till the patient has reached middle or advanced life, and it has been suggested that the condition is due to a contraction—possibly reflex in origin—of the muscularis mucosæ or of the circular muscular coat. That some of these cases are possibly congenital in origin, however, seems likely from the three instances quoted by von Ziemssen,[7] in all of which dysphagia had been noticed since childhood. One was a case under the care of Everard Home,[8] that of a female, aged 46 years, who died from lack of nourishment owing to increased difficulty in swallowing, caused by a uniform circular contraction of the mucous membrane at the entrance of the œsophagus, the appearance of which was normal. The second, recorded by Cassan,[9] was that of a man, 77 years of age, who, although suffering from some dysphagia all his life, had only marked symptoms during his last year, when ulceration in the mouth, caused by a silver toothplate, had extended downwards into the œsophagus. A circular ring of mucous membrane with a puckered edge was found in the upper part of the gullet and below this a narrow canal, eight millimetres long, in which the mucous membrane was cast into longitudinal folds. The third, which was reported by Zenker, occurred in a woman, aged 66 years, who died from carcinoma of the pylorus. In the upper part of the œsophagus was a circular contraction, over which the mucous lining was pale, delicate, and freely moveable on the submucosa.

6 Stenosis of the lower end of the œsophagus, cases like our own. Such a condition seems to be excessively rare and after searching through the literature we have only been able to find records of six cases that are at all analogous. The earliest is mentioned by Blasius,[10] but of the details nothing is known beyond that there were two strictures at the lower end of the œsophagus with a curious saccular dilatation between them. Cruveilhier[11] figures a stenosis extending down to the cardiac orifice of the stomach but merely says that the case in many respects resembled that of Cassan mentioned above. In the dilated portion of the œsophagus above the stricture were numerous polypoid vegetations. Wilks[12] gives a fuller account of a man, 74 years of age, who died from pneumonia. He had had difficulty in swallowing and regurgitation of food since childhood and at the necropsy the lower portion of the

[12] Transactions of the Pathological Society, vol xvii., p. 138.

œsophagus was found to be stenosed the lumen scarcely admitting the little finger Above the stricture the œsophagus was hypertrophied and dilated Hilton Fagge[13] records a somewhat similar case in a man, aged 84 years, though in this instance no dysphagia was noticed till after 40 years of age The lower end of the œsophagus presented a stricture on the upper part of which a recent epithelioma had arise ind dilatatior to the belief C Turner's ied from inanition At the lower end of the œsophagus, involving the cardiac orifice, there was a tight stricture which just allowed a No 2 catheter to pass There was no other malformation

A more recent case was described by B H Rogers[14] who has kindly furnished us with some additional details The patient was a male infant, one year and ten months old, who began to suffer from frequent vomiting about a year previously The condition became rapidly worse and was accompanied by emaciation A soft bougie was passed on several occasions into the stomach, for the tip came up acid, but on others it curled up on meeting the stricture Most of the food entered the stomach but part seemed to be retained in the œsophagus and it was sometimes several hours before it was returned Attempts at diagnosis by means of the x rays were not fortunate The child was fed on sponge cake mixed with carbonate of bismuth but no recognisable shadow could be seen The patient died from bronchitis and at the post-mortem examination a fairly tight stricture was found about an inch from the lower end of the œsophagus *The child's weight was 16 pounds 9 ounces*

The rarity till now of congenital lesions of the œsophagus causing stricture seems fully established by our researches into medical literature, but it remains for time to prove whether they are so uncommon as the paucity of recorded cases tends to show Now that attention has again been drawn to the condition by Rogers s and our own case it may well be that accounts of other cases will be forthcoming Until a comparatively short time ago congenital hypertrophic stenosis of the pylorus was an unknown condition but many instances of this lesion have been recorded during recent years and operative treatment has been undertaken with a fair amount of success It is, perhaps, not too much to hope that with improved methods of diagnosis cases of congenital stenosis of the œsophagus may be earlier recognised and that operative skill may effect their alleviation, for we cannot but think that such cases are not so few and far between as the records indicate At all events it is desirable that as many instances as possible should be recorded, so that an adequate explanation of their origin may be arrived at and definite lines for surgical treatment laid down, for hitherto efforts in this direction have been entirely unsuccessful It may be that stricture at the commencement of the œsophagus is caused by excessive narrowing of the fore gut where it contracts to form the gullet, as it has been shown by Balfour and Meuron that in most vertebrates—mammals excepted—at a certain period of development the lumen of the œsophagus becomes for a time completely obliterated at its upper extremity, and even in the human embryo at an early stage the cervical portion of the œsophagus exists only as a column of later becomes channelled the development of the the stenosis of its lower end Is it possible that our knowledge of the development of the alimentary canal is still incomplete and that further investigations in this direction are required?

In the *reports of the different cases recorded here and* in the references obtained from the different indices and catalogues in the library of the Royal College of Surgeons of England and elsewhere we can find no discussion or opinions on the surgical treatment of congenital stricture of the œsophagus In cases like ours where the stricture is low down, it seems that the alternatives are dilatation with bougies and gastrostomy, for division of the stricture must be regarded as too risky a procedure and electrolytic treatment as doubtful in efficiency

Experience of gastrostomy in children for stricture of the *œsophagus following corrosive inflammation is not entirely* satisfactory, the local irritation of the skin and other discomforts making life for the child almost unbearable, so here as it had already been possible to introduce a small bougie we decided in consultation that dilatation with bougies was more rational and probably likely to succeed, as the stricture did not seem either long or very inelastic It was proposed to dilate further to a 15 size catheter and it was hoped that after this the occasional passage of a full sized bougie would maintain a sufficient opening Otherwise, as it would be impossible to insure frequent dilatation with bougies for a prolonged period in a hospital child we decided to resort to gastrostomy if a rapid relapse followed There is no doubt, as was fully demonstrated by the post mortem examination, that anything like satisfactory and lasting dilatation of the stricture with bougies would have been impossible and that had the child lived gastrostomy would have been inevitable

VICTORIA HOSPITAL FOR SICK CHILDREN

A CASE OF PRECOCIOUS LACTATION IN A MALE CHILD.

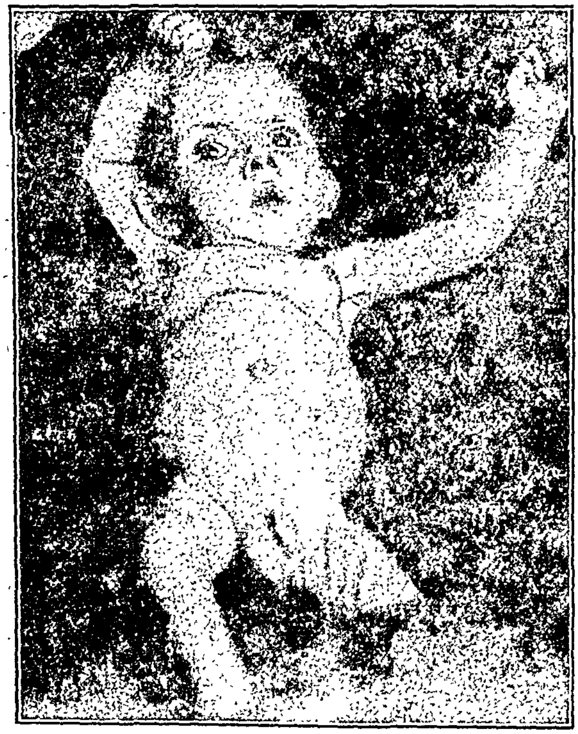
(Under the care of Dr MONTAGUE MURRAY.)

FOR the notes of the case we are indebted to Mr Robert M McQueen, clinical assistant at the hospital

The following case seems worthy of recording on account of this most unusual condition in a male child The patient, a male child, aged three and a half months, was admitted *into the Victoria Hospital for Sick Children* on July 8th, 1904, under the care of Dr Murray, for congenital morbus cordis from which he died on the 29th On were found to be enlarged to about all (the left being slightly larger were prominent and well marked, and the nipples were enlarged in proportion to the size of the breasts A fluid resembling milk was oozing from both nipples On palpation both breasts were firm and a well-marked mass of gland substance with an irregular outline could be felt There was neither pain nor tenderness Two or three drops of this milk like fluid could be squeezed from each nipple The child was breast fed and above the average size for his age having the appearance of an infant of from ten to 12 months old, the head was well formed the anterior fontanelle was nearly closed, and at death, three weeks after, was quite closed The genital organs were normal, both testicles were in the scrotum and of about the size of large cob nuts, and the penis was large *for the age* of the child The mother said that she noticed that the child s breasts began to swell when it was five or six weeks old and had gradually got bigger " She had never rubbed them nor had there been any nipple pulling and she had not noticed any swelling, pain, or tenderness of the breasts during the first week after birth During the three weeks the child was in the hospital until he died nothing was done to arrest the secretion, the breasts continuing to increase in size and to secrete

Necropsy —A post mortem examination was made and beyond evidence of congenital morbus cordis nothing was otherwise found Both breasts on section fully bore out that they were lactating breasts, which they appeared to be during life, the gland substance was *healthy and had every appear*ance of actively secreting glands, no cysts were present, there was no excess of blood, no injection lymph, or œdema, or any sign of active inflammation The ducts leading from the glandular substance were generally enlarged and irregular Unfortunately microscopical sections were not *made* The secretion was examined microscopically and was found to resemble milk except that there were fewer fat cells, in each field of the microscope one or two colostrum corpuscles could be seen

Remarks by Mr McQu between mastitis with lactation Sheild say associated with secretion and that the milky exud of some infants is ent central cells of the colur primary gland is formed He also quotes the case of a female child 16 days old whose right breast was opened for an abscess A milky secretion was seen issuing from the left breast This secretion under the microscope resembled maternal milk except that the latter contains more corpuscles.[1] That this case was not one of spurious lactation is borne out by the appearance of both breasts on section and the microscopical examination of the milk together with the absence of any tenderness, pain, or redness, or of any evidence of œdema or enlarged lymphatic glands; moreover, there was no history of irritation or injury and the breasts continued to enlarge and to secrete as long as the child lived. It seems probable that as the lactation did not begin until the child was five or six weeks old, it was not excited by a primary mastitis, a condition not infrequently found in infants a few days after birth. In further favour of this argument we find other evidences of precocious development in the unusually large sexual organs and the closure of the anterior fontanelle (*vide* illustration). There are several cases recorded of developmental precocity in female children. In one, a female child had great enlargement of the mammæ and menstruated under two years of age.[2] But I can find no mention of precocity of lactation similar to this instance, which, together with the fact that it occurred in a male child, seems to lend an additional interest to the case.



The illustration is reproduced from a photograph which was taken a few days before the child died after considerable wasting of the tissues had occurred, but shows the mammary enlargement, especially the right breast, and the abnormal size of the external genital organs.

OMDURMAN CIVIL HOSPITAL.

A CASE OF SWORD WOUND OF THE HEAD.

(Under the care of Mr. E. S. CRISPIN.)

THE patient, an Arab of fine physique, was admitted into the Omdurman Civil Hospital on Sept. 3rd suffering from a severe wound of the vault of the skull inflicted by a sword, with comminuted fracture and hernia cerebri. The injury had been inflicted on the night of August 31st, so that nearly three days had elapsed before admission; the first dressings had been applied by a native barber. The man performed the journey in a boat and was carried to hospital on his bed.

On admission there were signs of fairly free hæmorrhage, the patient was conscious but lethargic, his pupils were even and reacted to light, he had no obvious paralysis, and seemed in no particular pain. He had no incontinence of urine or fæces, was constipated, and his urine was drawn off by a catheter for the first 24 hours. He was unable to answer questions but seemed to understand when spoken to. The wound commenced about an inch over the left eyebrow and continued in a curved direction over the left parietal bone to about one and a half inches from the left occipital protuberance where it again took a sharp curve round towards the left ear. The total length of the wound was six and a half inches and its width in the centre was one and a half inches. The greater part of the left parietal bone was elevated half an inch; a quantity of brain substance, which was sloughing, protruded.

Immediately on admission the head was shaved, the wound was explored and some splinters of bone were removed, and clean dressings were applied; no attempt was made to bring the edges of the wound together on account of the sloughy condition of the brain and the elevation of the parietal bone. The accompanying illustration (Fig. 1) gives some idea of the condition of the wound some days after admission. There was no pus in the wound but a

[1] Diseases of the Breast, p. 57.

[2] Ibid., p. 59 (Meckel's Archiv für Anatomie, 1827).

copious discharge of cerebro-spinal fluid was present. A few days after admission there was some œdema of the eyelids and Mr. Crispin prolonged the incision downwards about half an inch and discovered a bead of pus; a fine gauze drain was inserted in this corner of the wound and a tight capeline bandage was applied, the œdema disappearing in a few days.

For 25 days the man remained in this lethargic condition, unable to speak; at the end of this time, in answer to a question, "How are you?" he answered "Taiib," which means "All right." But on trying him further, with "What is your name?" or "Put out your tongue," his answer was still, "Taiib." His friends put similar questions to him but the same answer was given to all. This peculiarity of speech lasted for 15 days more, during which time it was difficult to make him understand things. He had to be told several times to put out his tongue or to shut his eyes but eventually did it all right. At the end of this time—that is, about Oct 13th—more than six weeks after the infliction of the injury, he began to answer questions properly but very slowly, hesitating and stammering over them as though trying to remember a lesson; he used to hesitate even in giving his own name. From this date, however, there continued a steady improvement. He never had any apparent weakness in his grip or loss of movement anywhere. The part of the cortex that sloughed away must have been the centres for the head, eye, and arm to a great extent. The patient was altogether ten weeks in hospital and left with no other sign of injury than the scar.

Remarks by Mr. CRISPIN.—I think this case is worth recording on account of the enormous extent of the injury resulting in complete recovery with practically no surgical interference. It is improbable that a European would have survived this injury, but a native, with his less susceptibility to pain and shock and his fine constitution, frequently recovers in what at first sight appears a case of fatal injury. It will be interesting to hear whether the patient later develops epilepsy, as so often occurred in cases of bullet wound of the br[illegible] var which apparently at the [illegible]

The second illu[illegible] nt of the scar on discharge from hospital. Both photographs were very kindly taken for me by Mr. Turstig and Father Ohrwalder of Omdurman.

Medical Societies.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Election of Officers.—Fatal Lepto-meningitis.—Exhibition of Specimens and Instrument.—Tinnitus.—Internal Ear Deafness.—Cerebral Abscess.—Restoration of Hearing after Removal of Drum and Ossicles.

THE fifth annual meeting of this society was held on Dec. 5th, 1904, Dr. THOMAS BARR being in the chair.—The following officers were elected:—President: Dr. Thomas Barr. Vice-Presidents: Mr. A. E. Cumberbatch, Mr. John B. Story, and Mr. E Cresswell Baber. Honorary Treasurer: Dr. Edward Law. Honorary Librarian: Dr. Herbert Tilley. Honorary Editor of "Transactions": Dr. W. Jobson Horne. Council: Dr. Urban Pritchard, Dr. Arthur L. Whitehead, Dr. A. Logan Turner, Mr. Arthur H. Cheatle, Mr. Richard Lake, and Mr. [illegible] Secretaries: Mr. Hugh E. J[illegible]

An ordinary [illegible] eld.

Mr. A. E. CUMBERBATCH read notes of a case of Fatal Lepto-meningitis following upon acute suppurative otitis media of influenzal c[illegible] us lateralis were explored by [illegible] A small quantity of pus was [illegible] none in the sulcus or on the upper surface of the tegmen tympani No symptoms of any kind, except a rise of temperature to 106° F., followed the operation. At the necropsy purulent lepto-meningitis was found but no direct connexion between it and the focus in the temporal bone could be traced. Mr, [illegible] embers as to whether [illegible] a case.—Dr. WILLIAM [illegible] rachnoid space might [illegible] pointed out that in many of these cases the pus lay between the pia mater and the brain and that it was then practically impossible to drain away the pus but that occasionally where there was a localised collection of pus between the arachnoid and the dura mater it was possible to obtain a good result by operation. Mr. Ballance also remarked that meningitis occurred in influenza independently of an ear disease.—Dr. J. DUNDAS GRANT referred to the recent paper of Lermoyez, in which he advocated repeated lumbar puncture in the treatment of otitic meningitis.—Mr. HUGH E. JONES described two cases which illustrated Mr. Ballance's remarks; extensive removal of bone and multiple punctures of the pia mater had failed to drain the pus or to prevent extension of the suppuration.

Dr. ALBERT A. GRAY demonstrated by means of lantern slides the following specimens: (1) the Human Membranous Labyrinth, showing an accessory ampulla in the horizontal canal and supernumerary otoliths or calcareous deposits in the labyrinth; (2) the Membranous Labyrinth of the Seal, showing the large size of the organ and the large otoliths; (3) a section of the Cochlea of the Mouse; (4) a section of the Organ of Corti of the Mole, showing the spiral arrangement of the nerve termination at the base of the hair-cells; and (5) a section of the Cochlea of the Guinea-pig. In reply to a question Dr. Gray said that his method of preparing the labyrinth was described in the *Journal of Anatomy* two years ago.—The PRESIDENT, Dr. URBAN PRITCHARD, Dr. MILLIGAN, Dr. W. JOBSON HORNE, and Mr. P. MACLEOD YEARSLEY discussed the specimens.

Mr. RICHARD LAKE exhibited an Oto-masseur driven by a Turbine (Ash)

Dr. E. FURNISS POTTER read notes of a case of Severe Tinnitus, with almost complete loss of hearing, in a male, aged 21 years. Drug treatment had proved valueless. Dr. Potter asked for advice as to whether operative measures should be adopted—e.g., removal of cochleæ or division of auditory nerve.—An interesting discussion followed in which the speakers appeared to be unanimously of opinion that the tinnitus being diffuse and not "referred" to the ears, and there being an absence of any precise knowledge of the cause of the tinnitus, operation was not justifiable.

Mr. ARTHUR H. CHEATLE read notes of a case of Internal Ear Deafness of sudden onset. The patient, a middle-aged female, noticed loud noises in her ears after she had been yawning seven or eight times. The "noises" lasted from 20 to 30 minutes, when she found that she was deaf in the left ear, and it had a "dead feeling." There was no giddiness. The deafness had remained and occasional "noises" were heard. Examination of the ear revealed nothing beyond marked nerve deafness.—The case was discussed by Dr. MILLIGAN, Dr. DUNDAS GRANT, and others.

Dr. A. L. WHITEHEAD read notes of a case of Acute [illegible] boy, aged 14 years, who had [illegible] 12 months. He was seized [illegible] ours and coma lasting three [illegible] lled with pus and granula- [illegible] performed with subsequent exploration of the temporo-sphenoidal lobes on both sides. The result was negative but 36 hours later pus and sloughing brain material were evacuated on the right side and recovery followed.

Mr. CHARLES J. HEATH read a paper (founded upon an experience of 400 operations) on the Restoration of Hearing after Removal of the Drum and Ossicles by a modification of the radical mastoid operation for suppurative ear disease.—This paper was published in THE LANCET of Dec. 24th, 1904, p. 1767. Its discussion was adjourned to the next meeting.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Dec. 20th, 1904, Dr. T. Vincent Dickinson, the President, being in the chair.—Dr. R. L. Bowles read a paper on the Treatment of the Apparently Drowned, with a Practical Demonstration of the Best Methods of Resuscitation. The method advocated by Dr. Bowles was a modification of that originally introduced under the name of Dr. Marshall Hall, for whom in 1856 Dr. Bowles and others had carried out a series of experiments on the dead body. The three points chiefly insisted on by Dr. Bowles and now amply demonstrated by dissections on the dead body, by experiments on living animals, and by the experience of actual cases of drowning are the following: 1. That fluids are drawn into the lungs by the efforts at inspiration and that it is the presence of fluid in the lungs which is in most cases the immediate cause of death in drowning. 2. That the prone position is the only one that can be relied on for emptying the lungs of fluid and that this process of emptying the lungs must, on account of the inspissated character of the fluid from the admixture of blood, mucus, and saliva, be continued throughout the whole period of treatment. 3. That more air can enter the lungs through the aperture of the pharynx with the mouth shut than with it open. The method advocated by Dr. Bowles consisted of three separate movements. The first movement was to place the patient in the prone position and to employ firm but gentle pressure on the back of the ribs for three or four seconds. The pressure must then be suddenly removed to allow the entrance of air on the recoil of the ribs. In this position the tongue fell forward, leaving the entrance to the windpipe free for air to enter the lungs and fluid to leave them. The second movement consisted in grasping the patient's left shoulder and rolling him on to his right side. This movement should be repeated every, two seconds for about ten minutes. In this position the heart was left free and the liver did not press down on the heart and lungs. The third movement, which was to be employed if natural respiration had not been induced by the second, was an amplification of the latter. Instead of returning the patient at once to the prone position, the left arm was raised above the head until it was in a line with the body and brought back again to the side before the prone position was resumed. This movement assisted the expansion of the chest and allowed the air to enter the left lung more freely. These movements should be continued for an hour or until signs of natural breathing began.

Windsor and District Medical Society.—A meeting of this society was held on Dec. 21st, 1904, Mr. J. Brickwell, Vice-President, being in the chair.—Dr. George F. Johnston read a paper on the Nature of Hysteria. Arguing from the fact that hysterical patients can do without sleep for a very considerable period without suffering much from the lack of it, he suggested that the explanation of this might be that part of the brain of such patients was really asleep, or in a condition allied to sleep, all the time. He then alluded to cases of prolonged sleep, of trance, of ambulatory automatism (which he distinguished from post-epileptic automatism, giving examples of each to illustrate his meaning), and to cases of dual consciousness, all of which conditions he considered to be manifestations of hysteria and due to a partial or complete condition of sleep, affecting more or less continuously the whole or separate parts of the central nervous system. He further argued that such a condition would suffice to explain almost all, if not all, the manifold symptoms of hysteria. In order to do this, however, it was necessary to assume that the sleeping cells might be very few and it must also be recognised that higher and lower cortical centres, basal ganglia, cerebellar cells, and cells in the medulla and spinal cord might all be subject, separately or in combination, to this peculiar condition of abeyance of function or abnormal sleep. From this it followed that a "rousing" method of treatment should be adopted for hysteria. Hence the value of electricity, especially faradisation. He suggested as a definition of hysteria "a condition of instability of the nervous system in which certain groups of cells or combinations of groups of cells are liable to fall into a state of abeyance of function or sleep, leaving subordinate centres to act automatically and uncontrolled."—A discussion followed to which Mr. J. W. Gooch, Mr. W. J. Handfield Haslett, Mr. T. G. Drake, and Dr. G. E. Hale contributed.—The proceedings terminated with a vote of thanks to Dr. Johnston for his valuable and interesting address.

Reviews and Notices of Books.

The Life of Richard Wagner. By William Ashton Ellis. London: Kegan Paul. 1904. Vol. IV., pp. 537. Price 16s.

This is the fourth instalment of a voluminous biography written by a member of our profession. Mr. Ellis is an enthusiastic devotee of the Wagnerian cult and the reader will find evidence in every page of painstaking research. The period covered in this volume is barely two years—viz., 1853 to 1855—of the composer's life. Wagner was born in 1813. At the age of 19 years he wrote a symphony (his first composition having been an overture which was performed in 1830) and his first work for the operatic stage was *Die Hochzeit* in 1833. It was not till 1842 that the more generally known operas began to appear. Thus *Rienzi* was performed in 1842, *The Flying Dutchman* in 1843, *Tannhäuser* in 1845, and *Lohengrin* in 1850. From the first he was his own librettist and he always devoted considerable time to the writing of the "poem" which he intended to illustrate in "tone-colour."

In the volume under notice we have the history of his beginning the music of his *magnum opus*, "*Der Ring des Nibelungen*," the poems of which he had been elaborating since 1845. There is an interesting description of the discovery, owing to Mr. Ellis's careful investigations, of the fair copy of the poem of the Dresden *Siegfried's Tod*, written in the composer's own handwriting as a "revise" a few months after the original MS. of 1848. It had been given by Wagner to his friend Sulzer as a "keepsake," but the recipient died in 1897 and his family were unaware apparently that such a treasure was in their possession. (*Siegfried's Tod* is now generally known as *Götterdämmerung*, the fourth part of *Der Ring*, the first three parts being *Das Rheingold*, *Die Walküre*, and *Siegfried*. Though in four parts, the whole work is alluded to as a "trilogy," *Das Rheingold* being considered the prologue.) In 1853 Wagner, an exile from his country (on account of supposed connexion with political intrigues), was living at Zürich. It was there that the first "Wagner Festival" took place. With considerable difficulty he got together an orchestra capable of performing selections from *The Dutchman*, *Tannhäuser*, and *Lohengrin*. A week before the concert he gave readings of the "poems" to a "freely invited and non-paying audience," so anxious was he to demonstrate the close connexion between music and words (Chapter III.). This festival was a great success from a musical point of view but the composer was depressed, physically and mentally, as is shown by his letters to Liszt and others. The loneliness of expatriation worried him, overwork was causing insomnia and lassitude, and financial difficulties added to his worries. Thus to Liszt he writes on May 30th, 1853: "I am very tired and knocked up"; and to Roeckel on June 8th of the same year, in speaking of his intentions for the future, "I have to gird up all my strength and health—which often is very ailing—to carry out the musical composition of my Nibelungen dramas." In another letter to Liszt he sums up his temperament in the following words: "I can live in nothing but extremes—the greatest activity and excitement and the most perfect calm."

What was the precise nature of Wagner's disabilities? We learn from the book before us, first, that he was the subject of a hernia "that necessitated the wearing of a truss (never properly adjusted according to the statement of his last physician)"; secondly, there was nerve-strain—"undiagnosed eye-strain," Mr. Ellis considers it to have been, and this is also the opinion of Dr. G. M. Gould.[1] For his neurotic symptoms he was recommended a sojourn in St. Moritz and thither he went in July, 1853. But he did not derive much benefit therefrom, for he wrote: "I'm too restless to be able to abstain for long from all activity; in short, I am no 'cure' subject—I have found out that—now I'm burning to go to Italy." And to Italy he went—a hurried visit—for he returned to Zürich in September, complaining of "loneliness," insomnia, and consequent "melancholy." He was longing to resume the composition of *Das Rheingold*; abstention from work was apparently more trying to him than the overwork which had produced his illness. Thus in January, 1854, he writes to Liszt: "During this work I often felt quite well; the storm clouds seemed to have wholly cleared." And a few weeks later his letters are full of despondency and longing for death. He lived, however, for nearly 30 years after that date. His visit to London to conduct for the Philharmonic Society took place in February, 1855. Particulars of this will form part of the next volume but it may here be recalled that his reception was anything but enthusiastic. His work was ironically termed the "music of the future" by most of the critics, but there is no denying the fact that his admirers and worshippers are now legion, and to them this detailed biography will prove most interesting.

---

[1] Biographic Clinics, vol. ii. See also The Lancet, August 1st, 1903, p. 306, and March 7th, 1903, p. 672.

Pathological Technique: a Practical Manual for Workers in Pathological Histology and Bacteriology, including Directions for the Performance of Autopsies and for Clinical Diagnosis by Laboratory Methods. By FRANK BURR MALLORY, A.M., M.D., Associate Professor of Pathology, Harvard University Medical School; First Assistant Visiting Pathologist to the Boston City Hospital; Pathologist to the Children's Hospital; and JAMES HOMER WRIGHT, A.M., M.D., Director of the Clinico-Pathological Laboratory of the Massachusetts General Hospital; Instructor in Pathology, Harvard University Medical School. Third edition, revised and enlarged. With 156 illustrations. London and Philadelphia: W. B. Saunders and Co. 1904. Pp. 469. Price 13*s.* net.

THAT three editions and a reprint should have been called for in seven years sufficiently attests the value set upon this work in the United States. Apart from this, however, anyone acquainted with recent American writings on pathology must have remarked this appreciation, as references to, or extracts from, the work of Mallory and Wright are to be met with constantly. The scope of the book is extensive as it deals with the practical methods employed in morbid pathology, histology, and bacteriology. Indeed, the work goes beyond what is indicated in the title, for not only is the technique of laboratory methods described but, in some cases at least, the deductions to be drawn from the observations are discussed. It could only be by a rigid selection of such methods as have proved of distinct service in practical work and by cutting out all antiquated or unpractical matter that the subject could be treated within the limits of what is, after all, only a book of moderate size. As might be expected from the authors, the selection of methods is judicious and the whole treatment of the subject is such as to leave but minor points open to criticism.

The book is divided into three parts, treating respectively of post-mortem examinations, the technique of bacteriology, and the methods used in pathological histology. The instructions for the performance of necropsies are eminently practical, though some suggestions are not entirely suitable to English conditions. In the bacteriological section we notice that the preparation of agar is still spoken of as troublesome but most of the difficulties in filtration disappear with the proper use of the autoclave and of suitable filter paper, so that agar will filter as quickly as gelatine. Protest must be made, too, against the use of the term "superheated" as applied (p. 89) to the steam in the autoclave, as there is risk of a fundamental misconception since "superheated" steam has not the sterilising value of "saturated" steam. The steam in the autoclave is in this latter condition. Among Gram staining organisms the bacillus œdematis maligni is not usually grouped. One of the new methods introduced into this edition is Hill's "hanging block method" which does not seem to have any advantages over that described by Professor S. Delépine some years ago. The section dealing with special bacteriology is well arranged, clearly written, and the object of the book is kept clearly in view.

In Part III. several new methods are described, including one by Dr. Wright for embedding and manipulating frozen sections of small fragments of tissue. This appears likely to prove of considerable value to those who have to deal with scrapings and curettings of organs for diagnostic purposes. For the determination of the hæmoglobin in blood the method of von Fleischl is alone given, no mention being made of Haldane's hæmoglobinometer which is the instrument usually employed in this country. A new blood stain has been devised by Dr. Wright which claims to be an improvement on those of Leishman, Jenner, and Ehrlich on the grounds that it is more easily and simply made while it possesses all the differential staining properties of these stains with the easy fixation associated with the methyl alcohol method. It should prove a valuable addition judging by the illustrations showing films stained in this way. There is also a new method by Dr. Mallory for neuroglia fibrils. Short accounts of inoscopy and cytodiagnosis have also been introduced.

The book is illustrated with woodcuts and numerous reproductions of photographs, some of which are taken from well-known works but many of which are original. With regard to these latter, while we recognise their excellence we cannot see the advantage of the excessive magnification (× 2000) employed. The microscopist rarely sees his specimens, at least in English laboratories, under a greater magnification than from 600 to 1000 diameters, and these highly magnified figures are therefore somewhat misleading while they lose at the same time the sharpness of definition which could be obtained with a lower power. There is a very fine reproduction of a segmenting malarial parasite in an unstained blood film. The book is well printed and does credit to the publishers.

The Röntgen Rays in Therapeutics and Diagnosis. By WILLIAM ALLAN PUSEY, A.M., M.D., Professor of Dermatology in the University of Illinois; and EUGENE W. CALDWELL, B.S., Director of the Edward N. Gibbs X-ray Laboratory, New York. Second edition, revised and enlarged. London and Philadelphia: W. B. Saunders and Co. 1904. 8vo, pp. 690. Price 21*s.* net.

THE full and favourable reviews which this work received on the issue of the first edition in 1903 make it unnecessary to describe it now at any great length. As was said then, this work is probably the best that has been published on this subject in the English language. The arrangement is the same as formerly. The first part is written by Mr. Caldwell and deals with x-ray apparatus and its use in diagnosis. It has been brought up to the date of going to press in January, 1904. The chapter on the choice of an x-ray outfit will be of the greatest value to those intending to take up this fascinating line of work. The whole of this section is very well done. The description of the various apparatus and practical methods is very clear and the numerous illustrations will be found of the greatest help to those whose experience has not been very extensive.

The second section is by Dr. Pusey and deals with the effects of the x rays on living tissues and the application of these effects in the treatment of disease. The changes produced in normal tissues form a proper opening to this section. These, both macroscopic and microscopic, are described in detail. Then follow the changes produced on diseased tissues and also on bacteria. Various methods of technique are fully described and in this chapter the special appliances necessary for x-ray therapeutics are indicated, including protections against the undesired effects of the x rays on both patient and operator. After dealing with the indications for the use of the x rays the author proceeds with the treatment of special diseases. At first sight Dr. Pusey's results in the treatment of cutaneous carcinoma are very startling. It is a fair criticism, however, that many of the cases which he records as "cutaneous carcinoma" would be regarded in this country as rodent ulcer. After making due allowance for this the author's results will be found to correspond practically with those obtained in this country. A valuable feature of this chapter is that the reports of the cases mentioned in the first edition have been brought up to date. On the whole, the results are encouraging. The author, while careful not to advise the substitution of the x rays for excision in operable cases, approves of the use of the rays as a prophylactic. This is a matter of very great importance and it is earnestly hoped that the use of the x rays after operation for malignant disease will be practised more generally and that recurrences will be less frequent. The work is thoroughly to be recommended. It is printed in clear type on good paper and the illustrations are numerous and excellent.

Les Rayons N et les Rayons N_1. (The N Rays and the N_1 Rays.) By Dr. H. Bordier. With 16 figures. Paris: J. B. Baillière et Fils. 1905. Pp. 95. Price 1 franc 50 centimes.

This is one of a long series of similar small manuals and deals with the Blondlot rays, sometimes called the "n" rays because Professor Blondlot, who discovered these rays, is a professor in the University of Nancy. Their discovery goes back to March, 1903, when Professor Blondlot whilst endeavouring to polarise the rays emitted by a Crookes's tube, found rays beyond the ultra violet, which rays, he stated, pass through aluminium, do not exhibit fluorescence, and, unlike the x rays, can be refracted. According to Professor Blondlot, these rays are emitted by a Welsbach light, a Nernst lamp, the sun, and even non-luminous bodies in a state of strain or compression—e.g., wood or steel. They are said to increase the intensity of a small flame. Many regard this increased luminosity as a subjective phenomenon due to a physiological change in the eye itself. An account is also given of those marvellous statements of Professor Charpentier that nerve and muscle in action emit these "n" rays and that the rays thus emitted affect a small luminous flame, making it more brilliant. In England, at least, not much credence is attached to the experiments of Professor Charpentier in this regard. The treatise is quite an elementary one and until verification of the phenomena which it describes is complete it is not likely to attract much attention on the part of medical readers, more especially as many physicists doubt even the existence of these much-belauded rays.

Biological Chemistry of Muscle and Nerve. Ten Lectures by W. D. Halliburton, M.D. Lond., F.R.S. (Published under the authority of the University of London.) London: John Murray. 1904. Pp. 160. Price 7*s.* 6*d.* net.

These excellent lectures are the outcome of two courses of lectures, one delivered in New York in January of last year by their author as the first Herder lecturer and the other delivered in the University of London. Three pages are required to set forth the titles of the principal researches published by the author or in conjunction with colleagues or carried out under his superintendence. The earliest paper dates from 1883 and the lectures may be taken as a *résumé* of the subjects with which they deal and the contributions made thereto by the author and his pupils. The real keynote of our knowledge of muscle proteids was struck by Willy Kuhne in 1864. Since then detail upon detail has been added and theories have been retracted. Kuhne also by using the muscular part of the diaphragm showed that the red colour of the so-called red muscles is due to the presence of hæmoglobin. Four lectures are devoted to muscle—its composition, heat [illegible] -proteids, ferments, extractives, and [illegible] chemical side, while in Lecture V. we find a short account of the chemical changes accompanying the contraction of muscle and the chemistry of tendon. The remaining five lectures deal with the nervous system under the following heads: chemical composition, metabolism, coagulation, temperatures of nerve proteids and its relation *inter alia* to hyperpyrexia, the chemistry of degenerative nervous diseases, and the degeneration and regeneration of nerves. The author regards the regeneration of nerve fibres as due to an outgrowth from the nerve cell and opposes the view of Bethe and others of auto-regeneration of nerve fibres. The white substance of Schwann is regarded as formed in relation to the axis cylinder and not by mesoblastic cells. Throughout the author has given full credit to those who have been his pupils and also to those who assisted him in actual experimentation. His joint researches with Dr. F. W. Mott and Dr. T. G. Brodie are set forth in an instructive form. Most of the results have already appeared either in text-books or lectures, so that there is no need to refer to the subjects in detail.

Atlas der deskriptiven Anatomie des Menschen. (Atlas of Descriptive Human Anatomy.) By Dr. Med. J. Sobotta, Extraordinary Professor and Prosector of Anatomy and of the Institute of Anatomy at Wurzburg. Second fasciculus. The Viscera, including the Heart. With 19 coloured plates and 187 illustrations (some in colours) from originals by K. Hajek (Artist). Munich: J. F. Lehmann. 1904. Pp. 169. Price M.16.

Grundriss der deskriptiven Anatomie des Menschen. (Essentials of Human Anatomy.) Second fasciculus. By the same Author. Pp. 155. Price M.3.

The atlas is the second volume of Dr. Sobotta's Atlas of Descriptive Human Anatomy and the descriptive letterpress appears as the second volume of Essentials of Anatomy by the same author. We have already noticed the previous issue of the same work and this one is in every respect similar to its predecessor. The atlas comprises 19 coloured plates and 187 figures besides. These are devoted to the viscera. The digestive tract stands first in order, the illustrations of the temporary, permanent, and developing teeth being particularly numerous, no less than 20 figures being devoted to this part of the subject. The salivary glands and the thyroid are illustrated in the same lavish manner. The usual views of the constrictor muscles of the pharynx appear and call for no remark. A very successful representation of the mutual relations of the œsophagus, trachea, bronchi, and great arteries is found in Fig. 302. The illustrations of the stomach, liver, spleen, pancreas, and kidneys are more or less familiar, being on the lines of the models by His. There are some good semidiagrammatic representations of the peritoneal reflexions and some figures showing the development and folding of the alimentary canal. The thorax is treated in a similar way to the abdomen and the plates which represent the right and left views of the mediastinum after removal of the lungs appear very useful. There is nothing very new in the illustrations of the pelvic viscera and the heart. The atlas is a good and painstaking production whilst the descriptive volume is accurate but by no means exhaustive.

Report on the Preparation of "Rinderpest Protective Serum." By Alfred Lingard, M.B., M.S. Durh., D.P.H. Cantab. Calcutta: Government Printing Office. 1904. Pp. 42.

As bacteriologist to the Government of India Dr. Lingard has had exceptional opportunity for studying the question of the value of different sera against the ravages of rinderpest in cattle and his report is a summary of the [illegible] to the present time. Dr. Lingard [illegible] valuable assistance received from Captain G. K. Walker and Captain J. D. Holmes of the India [illegible]

Civil Veterinary Department. The bile method of Koch was found to confer an active immunity lasting from two to five months, the bile of from three to seven animals being required to protect each hundred animals operated upon. Its action is not curative. The immunising effect of the bile injection begins on the fifth day and is not complete until the tenth day. It is curious to note that immunity against the disease by the use of rinderpest bile can be conferred upon plains bovines and plains and hill buffaloes, but not on the hill breeds of cattle. Edington's bile method can only in equivalent doses give a passive protection for a very limited period, as glycerine destroys the "contagium" of rinderpest. The injection of virulent blood after the injection of bile fails to prolong the period of protection already afforded. The injection of a quantity of fortified serum on one side of the animal's body and a small quantity of virulent rinderpest on the opposite side confers a considerable immunity and the serum has the following advantages over bile: it is cheaper, it can be prepared in large quantities, it can be kept, and it will not communicate any other disease. The actions of defibrinated blood and serum in animals are similar but the disadvantages of the blood are that it will not keep, it can communicate other diseases, and a very large quantity is required; its only advantage is that it can be utilised when no serum is procurable. Dr. Lingard discusses fully the methods of preparation of anti-rinderpest serum, the susceptibility of cattle and buffaloes indigenous to India, and the period during which the anti-rinderpest serum will retain its protective power after exposure to various temperatures. In an appendix some 50 tabular statements of the actual details of the result of one or other of the different methods employed are given, the whole report showing in a very condensed form the result of much labour in the field of preventive medicine.

LIBRARY TABLE.

The Anatomy of the Brain: a Manual for Students and Practitioners of Medicine. By J. F. BURKHOLDER, M.D., Professor of Anatomy in the Illinois Medical College and the Illinois Eye, Ear, Nose, and Throat College; Professor of Physiology in the Dental Department of the University of Illinois and the Dearborn Medical College. With 86 full-page plates. Chicago: G. P. Engelhard and Co. 1904. Pp. 174. Price $2.—The short title of this book is misleading, the brain described being that of the sheep. This brain has been chosen as an example on account of the ease with which it can be obtained and its resemblance to the human brain. No doubt a student who conscientiously works through the dissections described will gain a very fair knowledge of the naked-eye anatomy of a brain, but from a medical and pathological point of view nothing can ever replace a practical acquaintance with the brain of man. The plates, most of which are from the author's own drawings, are excellent and very clear but we have found the letterpress very difficult reading. Owing to the mixed terminology the book is neither English nor Latin and the Latin needs extensive correction, many errors having crept in. The revision of the book appears to have been very imperfect.

Medical Annals and Report of the Hamidié Hospital for Children, Constantinople, 1903-1904. Fifth year of publication. Constantinople, 1904.—The fifth issue of the reports of this hospital contains matter in French, German, and Turkish. The hospital besides being used for children also treats wounded soldiers. Among the notable articles is a most interesting one, unsigned, concerning "Hospitals in Islam," which gives an account so far as is possible of the celebrated one at Gondisapor which flourished in the eighth century. Dr. Salih Békir writes upon vesical calculus, which is common in Turkey. He gives details of 20 cases that came under his care at the hospital in two years. Of the 20 patients one was a girl. All the calculi were under ten grammes in weight except two, one of which weighed 14 grammes and one 45 grammes. The last named occurred in a male child aged six years. He was at first treated by means of rest, a milk diet, and Kara-Hissar water, and under this regimen the cystitis, which had at first prevailed, diminished. A lateral lithotomy was performed on June 9th, but the stone was found to be too big for extraction. On the 23rd the stone was removed by the suprapubic route. Some suppuration occurred but the child left the hospital on Sept. 19th completely healed and with no difficulty of micturition. The calculus was phosphatic.

Practical Nursing. By ISLA STEWART and H. E. CUFF, M.D. Lond. Edinburgh and London: William Blackwood and Sons. 1904. Pp. 432. Price 5*s.* net.—This admirable book was originally published in two volumes, the second of which appeared at some interval of time after the first published in 1899, and was reviewed in THE LANCET of Oct. 17th, 1903, p. 1099. The present edition is in one volume and, so far as we can remember, does not contain anything new. But the original edition was so excellent that practically nothing new was needed. We commend the book to all who have to do in any way with the care of the sick.

Practical Ambulance Tablets. By SYDNEY PARTRIDGE, M.D. Edin. Fifth edition. London: J. and A. Churchill. 1904. Pp. 71. Price 1*s.*—The continued demand for this little book is ample evidence of its merits. Dr. Partridge, who is an examiner and a lecturer to the St. John Ambulance Association, intends it to be a companion to the text-book of the association and it no doubt summarises very conveniently the chief points to be observed in the rendering of first aid. All the accidents and conditions described are urgent, hysterical unconsciousness excepted, and the directions given are intentionally very concise. A page or two might, however, have been devoted to advising rescuers as to their own protection when entering places filled with smoke or noxious vapours. There are eight pages of illustrations of conveyance of the injured, artificial respiration, and other kinds of first aid.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., W. F. R. WELDON, F.R.S., and SYDNEY J. HICKSON, F.R.S. With lithographic plates and engravings on wood. London: J. and A. Churchill. 1904. Vol. XLVIII., Part III. Price 10*s.*—The memoirs contained in this number of the journal are:—1. On the Existence of an Anterior Rudimentary Gill in Astacus Fluviatilis, by Margaret Moseley, with plates xxiii. and xxiv. 2. On the Development of Flagellated Organisms (Trypanosomes) from the Spleen Protozoic Parasites of Cachexial Fevers and Kala-azar, by Leonard Rogers, M.D. Lond., with one plate. Captain Rogers maintains that kala-azar is a severe form of malarial cachexia or cachexial fever. He depicts the divisional forms without development and the developmental forms which present themselves after development of one, two, three, and four days, and shows that the infection especially affects particular houses and is always extremely localised, removal to a new site half a mile distant proving successful in preventing the spread of the disease, which, he thinks, is effected by flies. 3. The Epithelial Islets of the Pancreas in Teleostei, by John Rennie, D.Sc., with three plates. He regards the islets as blood glands with internal secretion. 4. Observations on the [illegible] fertilisation of the Egg of the Axolotl, by J. W. [illegible] plates. 5. Notes on the Anatomy of the Gazelletta, by G. H. Fowler, B.A.

The Veterinary Journal.—In the December number of this journal we note that the paper is bidding farewell to Professor W. O. Williams, one of its editors, this gentleman having been appointed principal of the new Veterinary School in connexion with the University of Liverpool. The articles contributed include one on Natural and Conferred Resistance to Disease in the Animal Body, by Mr. Frederic Lewis, several clinical cases, numerous translations from the French and German periodicals, and a continuation of the article on Veterinary Toxicology by Colonel J. A. Nunn of the Army Veterinary Department.

Caledonian Medical Journal.—The opening article of the January number is a biography of Mr. Hector McColl of Tobermory in the Island of Mull, who was born in that island in 1799 and died in 1891. Dr. A. C. Miller, medical officer of health of Fort William, contributes a paper on Medico-legal Experiences in a Highland District; two of the fatal cases which he describes were due to attacks by infuriated cattle. Dr. David Rorie of Cardenden gives the puerperal history of a woman who, in eight pregnancies, had three times borne an anencephalic fœtus. One of the editorial paragraphs announces that the annual meeting of the Caledonian Medical Society will be held in Manchester next summer.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

CLINICAL THERMOMETERS (HALF-MINUTE OBSERVATION).

(JAMES J. HICKS, 8, 9, AND 10, HATTON-GARDEN, LONDON, E.C.)

SOME doubt has been expressed as to whether accurate observations of the temperature of the body may be made by employing quick-registering thermometers, limiting, say, the time of exposure of the thermometer to half a minute. The accuracy of the record depends upon the care with which the observation is made. It is well to bear in mind that in cold weather thermometers which presumably register the correct sub-lingual temperature by half-minute observations will take a longer time to register that temperature than when the external temperature is near the normal (60°F.). On the whole, however, the rapid-registering clinical thermometer will be found to record accurate results when certain simple precautions are observed. At least we have found such to be the case with a number of clinical thermometers (half-minute observation) sent to us by the above maker. These clinical thermometers possess the important advantage that the height of the column of mercury may be easily read owing to its magnification by the lenticular form of the capillary tube. In one experiment six thermometers, the temperature of the air being 63° F., were placed in a water bath at 102·4° for half a minute. The temperatures recorded by the six thermometers tested were respectively as follows: 102·4°, 102·2°, 102·4°, 102·2°, 102·4°, and 102·2°. The mean reading of the six thermometers was thus 102·3°, so that the greatest *minus* deviation was 0·1° and the greatest *plus* deviation 0·1° also. In the second experiment the temperature of the water bath was 96·8°. After immersion for half a minute the thermometers recorded the following results: 96·80°, 96·90°, 96·70°, 96·60°, 96·80°, and 96·75°. The mean result was 96·75° and the greatest *plus* deviation from the mean was 0·15° and the *minus* deviation 0·05°. Next the temperature of the body was taken by placing the thermometers under the tongue for half a minute. The readings were as follows: 98·1°, 98·2°, 98·0°, 98·3°, 98·0° and 98·0°. The mean was thus 98·10° and the greatest *plus* deviation from the mean was 0·2° and the greatest *minus* deviation was 0·1°. Next the thermometers were placed under the tongue of the same patient but for three minutes instead of half a minute. In all cases the column of mercury was reduced to just below 95° before the experiment was commenced. The results were as follows: 98·0° 98·1°, 98·1°, 98·1°, 98·0°, and 98·0°. The mean was thus 98·05° and the greatest *plus* deviation was 0·05° and the greatest *minus* deviation was 0·05° also. It will be seen that although the results in the three-minutes observation are closer than in the half-minute observation, yet for all practical clinical purposes the half-minute reading was as accurate as the three-minute reading. With quick-reading thermometers it is important that they should not be cold or below 60° F. before they are used. Observing these precautions it is evident from the above results that these thermometers are quite trustworthy for making clinical observations.

CREMANT DU ROI (SAUMUR VEUVE AMIOT).

(COCK, RUSSELL, AND CO., 36, GREAT TOWER-STREET, LONDON, E.C.)

We have on more than one occasion referred to the excellence of the sparkling wines produced in Saumur. There is no reason, we think, for regarding them as dietetically inferior to the wines produced in the Champagne district. The highly trained palate will detect a difference in the æsthetic qualities and that is all, but the majority of people would drink a good sparkling Saumur and find it just as pleasing as is a high-class and a high-priced champagne. Both the extra dry and the dry Crémant du Roi are excellent sparkling wines with the attractive character of a good champagne. The price is 45*s.* per dozen, On analysis the "very dry" specimen gave the following results: alcohol, by weight 12·38 per cent., by volume 15·30 per cent., equal to proof spirit 26·82 per cent.; extractives, 3·40 per cent.; mineral matter, 0·11 per cent.; volatile acidity reckoned as acetic acid, 0·18 per cent.; fixed acidity reckoned as tartaric acid, 0·65 per cent.; sugar, 1·90 per cent.; and ethers reckoned as ethyl acetate, 41·36 grammes per hectolitre. This is a pleasing, "clean" wine, free from volatile acid and containing a small proportion of sugar. The "dry" specimen gave the following results: alcohol, by weight 11·62 per cent., by volume 14·37 per cent., equal to proof spirit 25·18 per cent.; extractives, 4·37 per cent.; mineral matter, 0·11 per cent.; volatile acidity reckoned as acetic acid, 0·13 per cent.; fixed acidity reckoned as tartaric acid, 0·69 per cent.; sugar, 2·65 per cent.; and ethers reckoned as ethyl acetate, 48 grammes per hectolitre. The only important difference between the two wines is that implied by the distinctive terms "extra dry" and "dry," the latter having been liqueured a degree higher than the former. This is illustrated in the proportion of sugar shown in the analysis. Both are excellent sound wines.

CHELTINE MALTED MILK COCOA.

(CHELTINE FOODS AND CHOCOLATE, LIMITED, CHELTINE WORKS, CHELTENHAM.)

Our analysis of this preparation brought to light just the results which might be expected from the description given of its composition. It is made from cocoa, dried (full cream) milk, and a malted food. We found that nearly 40 per cent. of the food was soluble in cold water, while the fat amounted to 24·80 per cent., the proteid to 22·40 per cent., the mineral matter to 4·20 per cent., and the moisture to 6·75 per cent. It is practically free from unaltered starch. The above figures show this preparation to be a complete food and it follows from the particular method adopted in its preparation that it must be easily digestible.

BRANDIES (A. L. BOITEAU AND CO.)

(AGENTS: J. N. BISHOP AND SONS, 13, COOPER'S ROW, CRUTCHED FRIARS, LONDON, E.C.)

We have received three specimens of brandy described respectively as Fine Champagne (ten years old), Brut Cognac, and Liqueur Fine Champagne (25 years old). They all give results consistent with the description that they are grape spirit distilled in the pot still. The specimen of Fine Champagne ten years old gave the following results: alcohol, by weight 41·90 per cent., by volume 49·40 per cent., equal to proof spirit 86·56 per cent.; extractives, 1·74 per cent.; and mineral matter, 0·02 per cent. The secondary products, given in grammes per 100 litres of alcohol present, amounted to as follows: volatile acidity reckoned as acetic acid, 24·00; aldehyde, 6·50; furfural, 1·00; ethers reckoned as ethyl acetate, 128·48; and higher alcohols, 100·00; total secondary products, 259·98. The specimen of Brut Cognac gave the following results: alcohol, by weight 40·25 per cent., by volume 47·62 per cent., equal to proof spirit 83·45 per cent.; extractives, 1·65 per cent.; and mineral matter, 0·01 per cent. The secondary products, given in grammes per 100 litres of alcohol present, were as follows: acidity reckoned as acetic acid, 90·00; aldehyde, 10·00; furfural, 1·25; ethers reckoned as ethyl acetate, 122·80; and higher alcohols, 104·20; total secondary products, 328·29. For a Cognac brandy described as "brut" the amount of extractives is somewhat excessive. The Liqueur Fine Champagne 25 years old gave the following results: alcohol, by weight 41·80 per cent., by volume 49·29 per cent., equal to proof spirit 86·37 per cent.; extractives, 0·29 per cent.; and mineral matter, *nil*. The secondary products, given in grammes per 100 litres of alcohol present, were as follows: acidity reckoned as acetic acid, 60·00; aldehyde, 10·00; furfural, 1·50; ethers reckoned as ethyl acetate, 126·60; and higher alcohols, 120·00; total secondary products, 318·10. Here we should have expected in a brandy described as 25 years old more extractive matters and less furfural. The results throughout, however, indicate genuine brandies—that is, grape spirit distilled in the pot-still—and their æsthetic qualities are satisfactory and such as support the interpretation placed upon the analytical results.

VINCIGLIATA ITALIAN WINE.

(MORISON, POLLEXFEN, AND BLAIR, 34, LEADENHALL-STREET, LONDON, E.C.)

On analysis this wine gave the following results: alcohol, by weight 10·08 per cent., by volume 12·49 per cent., equal to proof spirit 21·89 per cent.; extractives, 2·58 per cent.; mineral matter, 0·19 per cent.; volatile acidity reckoned as acetic acid, 0·02 per cent.; fixed acidity reckoned as tartaric acid, 0·28 per cent.; and sugar, 0·15 per cent. This is a red Italian wine with a peculiar aroma and flavour but it is quite acceptable to the palate. The wine was practically non-acid and free from sugar. We believe it to be a sound, wholesome wine and it evinces slightly less "body" than usually characterises wines of this class and nationality.

MALTOFF.

(D. LAWRENCE & SON, 34, HIGH-STREET, HOMERTON, LONDON, N.E.)

This sweetmeat is described as malted cream toffee, a description with which we have no fault to find in view of the results of our examination. The toffee contains extract of malt, cream, butter, and cane sugar. The materials are evidently of a pure description and we could find no evidence of metallic contamination. The flavour is good, the toffee tasting pleasantly of malt.

ARGEX FLUID BEEF.

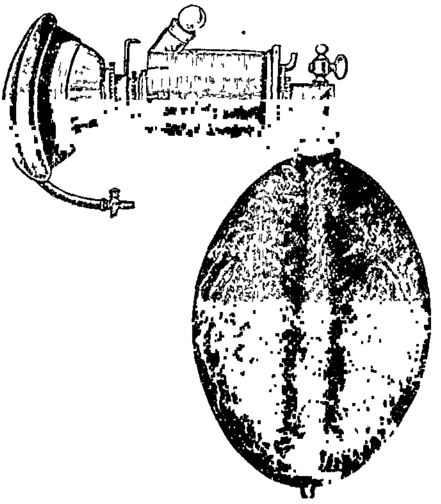
(THE ARGEX FLUID BEEF CO., 5, STATION BUILDINGS, ACTON-STREET, HAGGERSTON, LONDON, N.E.)

According to our examination this fluid beef is something more than a mere extract of meat, for it contains albuminous principles which are precipitated on adding bromine. The precipitate was voluminous. On quantitative analysis the following results were obtained: moisture, 53·47 per cent.; solid matters, 31·65 per cent.; and mineral matter, 14·88 per cent. On the addition of alcohol a precipitate was obtained amounting to one-fifth of the weight of the preparation. Peptones were present and in the sediment meat fibre was recognised. This fluid beef is a concentrated preparation of some merit containing reparative materials as well as merely stimulating extractives. The flavour is good and free from excess of seasoning or salt.

New Inventions.

A NEW FORM OF INHALER.

The inhaler shown in the illustration has been made for me in two sizes by Messrs. Arnold and Sons of West Smithfield, London, E.C., who have taken great pains in carrying out my wishes. It differs from the ordinary forms of Clover's inhaler in the following details:—The lid is removable, an arrangement which allows the interior of the body to be inspected and cleaned. The lid and the winged screw which fixes the lid are made of aluminium, which helps to reduce the weight. The lid lies on two indiarubber washers and when screwed firmly down forms with the top of the inhaler a watertight joint. The inner central tube has been made without the usual vertical partition, which diminished the airway by one half. By placing the windows of the inner tube near its upper extremity I find that the anæsthetic does not splash down the tube on to the face of the patient. The diameter of the central tube is one inch in the large and seven-eighths of an inch in the small inhaler and its windows are correspondingly large. The weight of the small inhaler is 1 pound 5 ounces. The angle piece has a short nozzle and tap for attachment of the indiarubber tube from a nitrous oxide bottle. The bag is made of red indiarubber and is reversible. The stopper is made of thick hollow glass, its neck being surrounded by a piece of red indiarubber tubing which, unlike vulcanite, is not destroyed by the anæsthetic. The stopper plainly indicates the amount of anæsthetic in the reservoir. The body is cylindrical and made of plated copper. There are two face-pieces, one large and one small, made of aluminium with inflatable rubber rims; aluminium being flexible, the face-piece can be easily moulded to suit various types of face. The stopper is the only part likely to break, and then only if extreme violence is employed. It is easily replaced. The threads of



the screws have been made extra deep. With the above inhaler I find it easy to administer all the ordinary anæsthetics, including ethyl chloride, and after removing the bag mixtures of chloroform and ether or chloroform alone. To use a different apparatus for each variety of anæsthetic is inconvenient and it is a great advantage to have an inhaler which can be properly cleaned and which is at any time available for the administration of all the ordinary anæsthetics.

A NEW RECTAL DILATOR.

THE accompanying illustrations show a new form of rectal dilator made on the same principle as Hegar's well-known uterine dilators. This set of dilators has been made for me by the Holborn Surgical Instrument Company, of 16, Thavies Inn, Holborn Circus, London, E.C., from whom the set of dilators can be obtained. They have the great advantage over any form of mechanical rectal dilator that no damage to the mucous membrane of the rectum can result from their use. They dilate perfectly gradually and smoothly and no force is required in using them. They are very much better than dilating bougies as being made entirely of metal they can be sterilised by boiling. Each dilator is four inches long and, except for the point which is cone-shaped, the sides are parallel. The handle is conveniently shaped to take the ball of the thumb. In using them the smallest size is introduced and allowed to remain till it is no longer nipped but can be withdrawn easily. The next size is then introduced and so on until sufficient dilatation has been obtained. It is possible with this instrument to stretch the sphincters sufficiently to paralyse them without administering an anæsthetic and without hurting the patient. I originally had these dilators made for the purpose of stretching the sphincters in cases of hypertrophy and spasm of these muscles; I have since found them to be of considerable value in a variety of other conditions.

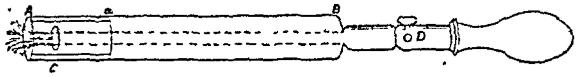
A NEW FORM OF VAGINAL ELECTRODE.

HAVING observed that sinusoidal currents when applied by electrodes in the form of a brush produced well-marked irritation of the skin, hyperæmia, and cutis anserina in cases in which electricity conveyed by the usual electrodes did not give rise to any phenomena either subjective or objective, it Bologna 1 to 530, in Pisa 1 to 530, in Naples 1 to 460, and in Pavia 1 to 330. In towns where there is no university occurred to me that this property of exercising an intensive irritant action might be useful in the treatment of disease when it was desirable to increase the blood-supply of the uterus and adnexa. In my first attempts an electrode in the form of a brush was introduced into the vagina through a speculum, but the process was tedious and not always practicable. I therefore devised an instrument in which an electrode and a speculum are combined. As shown in the illustration, the speculum is in this arrangement represented by a cylindrical vulcanite tube of the requisite length provided with a straight handle. The portion of the tube, *a* B, next the handle for about three-fourths of its length has a central perforation for conveying a copper wire, whilst the distal extremity, A *a*, is hollowed out into a wide recess in which a kind of piston carrying a brush can be moved to and fro for a short distance (limited by the nut C), so that the brush may at will be either fully drawn into the recess or may project at the end. During the introduction of the tube into the vagina the brush is within the recess until the desired part is reached; the tube is then drawn back, leaving the brush exposed and the current is turned on, the conducting wire being clamped by the binding screw D. When sinusoidal currents were employed in this way their power of attracting blood was quite perceptible but the results of the physiological observations must remain for future consideration.



Gynæcological Institute, Moscow. Dr. G. SNEGUIREFF.

THE SOCIAL AND ECONOMIC POSITION OF MEDICAL PRACTICE ON THE CONTINENT.

ITALY.

A FEW months ago[1] we gave our readers the result of inquiries addressed to friends in various continental countries with a view of eliciting trustworthy information regarding the various aspects of medical practice and the conditions under which it is carried on amongst those nations. The facts so obtained showed that the grievances complained of in our own country exist in an equal or an aggravated degree in France, Germany, and Austria, and it will be seen from the following account that the condition of the profession in Italy is no better. On account of the extraordinary cheapness of medical education in the latter country the proportion of students recruited from the poorer classes of the population is very large. The fees, taxes, and so on, for the whole six years curriculum do not amount to £40, including the cost of the diploma, whilst the expense of living in the university towns can be reduced to a very modest figure indeed. The ambition to belong to a learned profession and the opportunity thus afforded on such easy terms of rising in the social scale attract many to the study of medicine who in Great Britain would naturally gravitate into other and humbler walks of life. This tendency is the more marked because of the comparatively low industrial development to which the country has as yet attained and is noticeable in regard to the legal even more than the medical profession. Young men who in other circumstances would become bookkeepers or shop assistants or enter in some other capacity into industrial or commercial life are thus drafted into the medical profession in overwhelming numbers. The total number of medical men in Italy at the last census (February, 1901) was 22,168, or 1 for every 1460 inhabitants, but these figures do not give a just idea of the overcrowding of the profession in the kingdom, since the proportion in the villages is much less, every town or village of less than 10,000 inhabitants having the services of the *medici condotti* who are disseminated all over the country in a proportion of about 1 for every 2500 or 3000 inhabitants. In the large towns, particularly where a university exists, the ratio is much greater; for instance, in Catania it is 1 to 800, in Palermo 1 to 790, in Turin 1 to 610, in Genoa 1 to 600, in Padua 1 to 560, in Rome 1 to 550, in Florence 1 to 550, in the ratio is usually less, being in Milan 1 to 840, in Venice 1 to 900, in Verona 1 to 1020, in Bari 1 to 1040, in Leghorn 1 to 1200, in Lucca 1 to 1470, in Trajiani 1 to 1570, in Alessandria 1 to 1650, and in Ravenna 1 to 2000. It will thus be seen that another factor conducing to the overcrowding of the profession is to be found in the multiplication of medical schools which abound all over Italy and vie with one another in opening their portals as wide as possible. From these issue yearly hundreds of graduates who are let loose, as it were, into fields where the harvest is *not* plenteous and the labourers are already far too many. Indeed, for the vast majority the harvest to be gleaned pecuniarily is a very scanty one. We have already in a previous article[2] spoken of the *medici condotti*, who in the smaller towns and villages hold the medical practice almost exclusively in their hands. They number 12,000. Their salary is a very small one, varying from 1500 (£60) to 2500 (£100) or 3000 lire (£120) for attendance sometimes on both rich and poor, sometimes for attendance on the poor only, the better off among the inhabitants in the latter case generally paying a yearly capitation fee for medical treatment. As living in the country is cheap the existence of the *medico condotto*, if not free from financial cares, is still a comparatively easy one. Far otherwise is it with the ordinary practitioner in the larger towns. If attached to a hospital or university and enjoying a wide reputation he may indeed earn from 10,000 to 30,000 lire (£400 to £1200) per annum. Some are said to earn more, even as much as 150,000 lire (£6000) per annum. But such incomes are quite exceptional amongst Italian physicians and surgeons, whilst very many are even smaller than those of the *medici condotti* and in general the greatest dissatisfaction exists both with the amount of the annual income and with the often absurdly small amount of the visiting fee. For a single visit a fee of five lire (4*s.*) is reckoned tolerably good and one of ten lire (8*s.*) excellent. We are told on good authority that one or two fortunate men even receive a fee of 50 lire (£2) per visit, but such visits are probably "few and far between." On the other hand, according to the same authority, a fee of three lire or even two lire is very common, and, indeed, in some districts the unfortunate practitioner receives but one lira (10*d.*) per visit! The hardship of this miserable scale of remuneration for professional services is much aggravated by the frequency of bad debts contracted by the very poor and by the long delay on the part of richer patients in discharging their accounts. As in England patients often dispute their bills, well aware of the reluctance medical men feel in resorting to legal measures for enforcing payment. Except in the case of the *medici condotti* the system of yearly payments of a stipulated sum by families does not obtain. Friendly societies and clubs, who employ medical men at a fixed capitation fee, abound in Italy, but the tyranny which these bodies undoubtedly exercise has not yet raised such resentment in the profession here as it has in England; at all events it has not so far provoked any united action on the part of the "Ordini dei Medici," an association which performs much the same functions as the British Medical Association.

---

[1] THE LANCET, July 23rd, 1904, p. 242.

Quacks give very little trouble in Italy. The law is severe on quackery, punishing it by fine and imprisonment. But great harm is done by the encouragement which is freely given by a few members of the profession to quack nostrums, almost every newspaper containing objectionable advertisements of such remedies with testimonials to their efficacy from medical men whose portraits are often published to increase the *réclame*. The title of "Doctor" is bestowed on every medical man in Italy without regard to the origin of his qualification to practise. The distinctions made in Great Britain [illegible] not possess the right of calling [illegible] "Doctor." For this reason [illegible] he has no university [illegible] which becomes even a [illegible] Italian degree, since the fact would debar him from reaping the benefit of that provision in the law whereby a foreign practitioner is excused from attendance on classes and from certain parts of the examinations if he be a graduate of a foreign university of repute. The name of "Doctor" being thus so universally applied it has become a habit, especially amongst the lower classes who love titles of courtesy, to call every medical man "professor," even if he be not strictly entitled to that designation, to which, however, not only the holders of university chairs, but also their assistants and the numerous body of *liberi docenti* are legally entitled.

In Italy there is no sharp line of demarcation between the general practitioner and the consultant, especially in medical practice. The hospital physician who cultivates and obtains a consulting practice is almost always ready to attend as a general practitioner when called upon to do so and the same is true of most specialists. There are, however, consulting surgeons who decline to take cases without the consent of the practitioner in attendance. The fees charged by surgeons and specialists for operative work are remunerative but as a rule not excessive and sometimes, again, they are absurdly small.

The social position of the medical man in Italy is, on the whole, good, but the profession has suffered much in general estimation through the unfair treatment accorded to the numerous *medici condotti* by the communes employing them and the neglect of their well-founded grievances by the Government. These grievances, of which some account was given in the article already referred to,[3] have now been mostly remedied and the ground lost will doubtless be soon regained. The profession enjoys the advantage of being fairly well represented in the legislature, the newly elected chamber containing 22 medical deputies, and although there has sometimes been a tendency shown by those in Parliament to sacrifice the public welfare to their own supposed interests—as in the case of the attempted legislation against foreign practitioners—on the whole the country and the profession have alike benefited by their presence in the national assembly and many enactments having an important bearing on the public health of the community have been passed through their influence. This has been notably felt in regard to the sanitary law, to the work of midwives and their training,[4] to the measures against pellagra and malaria and for the gratuitous supply of quinine to the poor, and to [illegible] towns which previously were [illegible]

In connexion with the soc[illegible] Italy it will not be out of place to refer here to the admirable institution founded at Perugia through the initiative of Professor Ruata of that university for the orphans of medical men. In response to our request for information regarding this college Professor Ruata sends us the following interesting note: "Medical men in this country, though generally able to make ends meet financially, are for the most part far from rich and when one of them dies young leaving behind him a young family the poor widow and her little children are frequently plunged into abject poverty and great misery. To provide a remedy for such a sad state of things it occurred to me to found a college in Perugia for the orphans of medical men. Perugia seemed to me best adapted for this purpose not only as being most centrally situated and easy of access both from north and south but from the fact that it offers rare educational advantages with its university, elementary schools, gymnasium, high schools, technical schools, technical institute, normal school for teachers, Royal agricultural college, and school of fine arts for painting, sculpture, and music. The late King Humbert interested himself in the scheme, urging the immec[illegible] wish to succeed,' [illegible] with three or four orp[illegible] of a great institution, and do not think of large buildings but make a start at once.' Accordingly in 1891 the college was opened with five boys and only 4000 lire (£160) of capital. In 1898 the number of boys had increased to 21 and the capital to 100,000 lire (£4000), the principal source of income at that time being annual voluntary contributions of 5 lire each from about 1000 medical men. The progress already made had thus been most satisfactory but it became evident that the needs of the profession were immensely in excess of what could be provided by such means and it became necessary to find some other way of obtaining the requisite funds. The best plan which suggested itself was to impose a tax of 5 lire (4*s.*) by Act of Parliament upon every medical man practising in Italy, and after four years of incessant work [illegible] g of an Act which imposed this [illegible] in receipt of a salary, however small, from any public body. The income thus produced amounts to about 100,000 lire (£4000) per annum. There are now two sections in the college, one for boys, who [illegible] for girls, of whom there [illegible] from all parts of Italy." [illegible] by educating and training these poor orphans, not for professions but for trades by which they are all enabled on leaving the institution at once to earn a comfortable livelihood.

THE LANCET.

LONDON: SATURDAY, JANUARY 7, 1905.

The Army Medical Service.

As we announced last week, the King has been pleased to approve of the appointment of Surgeon-General Alfred H. Keogh, M.D., C.B., to the post of Director-General of the Army Medical Service. We also pointed out briefly that the appointment of Surgeon-General Keogh marked a new departure in that his selection for this important post was clearly not based upon seniority of service. We may assume that the War office in sending Surgeon-General Keogh's name to the King at the present juncture for this important and responsible post was accepting the recommendation of the Advisory Board whose intention it was to emphasise the policy of promotion by selection. In the correctness of this principle we must at once declare our belief; indeed, as the readers of this journal well know, it is one for which we have always, in what we conceived to be the interest of the public service, contended. One of the ablest and most independent Director-Generals who ever occupied that post was strongly in accord with this view, for it was one of the essential features of the Royal Warrant issued in the time of the late Sir William Muir that promotion to the upper ranks of the Army Medical Department was to be exclusively by selection, a method which, to the regret, as we know, of some of the best men in the Army Medical Service, fell more and more as time went on into abeyance. We have always considered that, however necessary the possession of military rank and titles might be found to be, the Army Medical Service must in the first place be regarded as a scientific branch of the army, that a way should always be kept open for the reward of professional merit, and that this should be counted as a more important factor in establishing a claim to promotion than was seemingly the case in days gone by.

Having so long held and advocated these views we can, while sincerely sympathising with the distinguished officers who, by virtue of their rank, seniority, and past services had earned an expectant title, as it were, to the post and whose legitimate hopes and ambition have been disappointed, honestly and consistently congratulate Surgeon-General Keogh on his appointment—an appointment which represents the adoption of a new and, as we believe, sound principle in this respect. In the various drastic changes which have been proposed or carried out in our whole army system since the late war in South Africa it became certain that the medical branch of that service would share. But it is obvious that at first sight the selection and promotion of a comparatively junior officer as best qualified for the post of Director-General, in the opinion of those who had the responsibility of making the appointment, over the heads of so many of his seniors was calculated to cause great surprise. The senior officers, be it remembered, had been previously selected for advancement to administrative rank and some of them had rendered very distinguished service in that capacity. We have turned to Surgeon-General Keogh's record of service. It is, undoubtedly, a good one and of a varied kind, but so far as his more military medical duties are concerned probably not better than could be shown by others. But it is to be noted that he has been chosen on several occasions to take part in the proceedings of War Office commissions and boards of a mixed kind in connexion with most responsible and important inquiries, and it seems clear to us, moreover, that he has on such occasions exhibited qualities which have most favourably impressed those with whom he has come in contact. We may assume, as we have said, that Surgeon-General Keogh was strongly recommended for promotion to his present post by the Advisory Board, a board which, it should be borne in mind, in addition to specially appointed civilian members, includes also military officers some of whom are army medical officers, and it may be fairly inferred that these latter concurred in the course adopted. It remains for the newly appointed Director-General to justify, as we feel sure that he will, the confidence that he has created and the distinguished honour implied by his selection in the exceptional circumstances of the case to the post which he now fills. He has our best wishes for his success.

◆

The Decline in the Birth-rate in New South Wales.

The decline in the birth-rate in this country of recent years is a matter of grave importance and is one which has long occupied the minds of those who take an interest in the future welfare of the British race. This decline in the birth-rate is to be found not only in almost all the countries of the Old World but has now spread to the countries of the New. The matter has, indeed, assumed such importance in New South Wales that last year a Royal Commission was appointed to inquire into the "decline in the birth-rate and the effects of the restriction of child-bearing on the well-being of the community." The commission carried out its inquiry with much completeness and its report, which has just been issued, is a document of great interest and importance. As a result of its statistical inquiries it confirmed the fact that there had been a very definite and marked decline in the birth-rate in the colony since the year 1889 and that the rate had exhibited a tendency to decline for a few years anterior to that date. The commission further found that such a decline was existent not only in its own colony but also in all the States of Australia and that a similar phenomenon was present in the birth statistics of most of the countries of Europe and in many of the large cities of the United States and South America.

The birth-rate in New South Wales began to fall in a most remarkable and sudden manner in 1889 and has continued to fall steadily until the year 1902, when the diminution amounted to as much as 10 per 1000 of the population. Further inquiry showed that there had been a rise in the marriage age during the years 1889–1902 which would in itself account for a slight fall in the birth-rate. Having proved to its own satisfaction that such a marked decline in the birth-rate actually existed the commission set to work to attempt to discover whether any condition existed which could be attributed to natural causes and which was sufficient to explain this remarkable fact. Its investigations failed to show any such natural cause. It found that the fall in the birth-rate was independent of any change in the age constitution of the population generally or in the age constitution of the women of the conceptive period, and that it was independent of such causes as any variation in the marriage-rate or any tendency to lessened fertility. Indeed, no adequate natural cause could be found and the commissioners were forced to come to the conclusion that the main factor causing the decline was to be found in some condition quite independent of natural causes and over which individuals had some control. In their endeavours to determine the character and nature of this force they examined a number of medical practitioners, including most of the leading medical men of the colony. The view which they finally adopted is in agreement with that held by the majority of the scientific writers who have discussed this difficult question of the falling birth-rate—viz., that it is due to the prevention of the results which nature has ordained to follow marriage, or, in other words, to the deliberate curtailing of reproduction by the prevention of pregnancy. This practice is not one of any recent growth but, if we are to believe the medical men who gave evidence before the commission, it has become excessively common of recent years amongst all classes of the community. Such a procedure is not only harmful, inasmuch as it leads directly to a diminution in the fecundity of the women who practise it, but the evil results which follow it lead in their turn to an absolute diminution in the fertility of these women. No doubt can be left in the mind of any intelligent observer that these practices are followed by results not only deleterious to the general health of the patients but also only too often by temporary and even permanent ill-effects on the genital organs of such a character as to cause ultimate sterility. Further than this, the commission found that there was a growing tendency to the procuring of criminal abortion and that this fact was also responsible in part, at any rate, for the decline in the birth-rate. The commissioners have no doubt that the reasons influencing those who practised limitation of the size of the family are such as generally prevail in all communities where these practices are found. Their origin is essentially a selfish one and although the adherents of this view are accustomed to still their consciences with the sophistry that it is for the good of the children themselves, as the parental means will not allow the rearing of a large family, yet the real reasons are to be found rather in the desire to avoid their proper duties and responsibilities. An unwillingness to assume the care of children, a disinclination to put up with the discomforts of child-bearing, and a selfish love of ease and luxury, which the expense of a large family might curtail—such are the real causes in the great majority of cases. That such doctrines should in the course of time spread even to young communities such as the States of Australia is not surprising when we bear in mind how widely spread and how widely practised these customs are all over the world.

It is extremely difficult to determine with any degree of accuracy what are likely to be the ill results to the bodily health of the women who practise such methods of prevention. The medical men who gave evidence before the commission were almost unanimous in laying stress on the evil results likely to ensue but we must bear in mind that the direct connexion between the practice of the prevention of pregnancy and the various gynæcological disorders which they held to follow these practices is one very difficult to prove. In the case of procured abortions we are on surer ground. That numbers of women are disabled every year by such procedures there can be no question at all, in fact, in only too many cases the death of the patient can be directly traced to such practices. Whatever may be the opinion as to the physical ill-effects which follow the prevention of pregnancy there can be no reasonable doubt as to the evil moral effects. As the commissioners point out in their report, "although criminality does not attach to the prevention of pregnancy, while it does to the procuring of abortion, yet both practices, as methods of avoiding procreation, are equally opposed to that morality upon which the welfare of the race essentially depends. They lower the standard of right living and thinking in a community, create laxity of morals, debase character, and ignore the sanctity of human life." Nor does the evil end here. The physical and moral advantages of large families are well recognised. Members of small families, like only children, are poorly equipped for the struggle of life and the avoidance of obligations and responsibilities on the part of the parents does away with a very powerful factor in the education of the individual. The importance of a rising birth-rate to the Commonwealth of Australia is all the greater, since the future of that Commonwealth depends to a very large extent on its ability to people its vast expanse of country. What the diminution in the growth of the population means to Australia will be realised when we recall the statement made in the report of the commission that had it not been for the reduction in the birth-rate and the excess of mortality amongst illegitimate children over legitimate children which have occurred in the period 1864–1902, the population of New South Wales would now be more than 250,000 greater than it is; while for the whole of Australia the approximate loss of inhabitants amounts to no less than 940,000. What the effect of such a loss of population means to commerce and the prosperity of the country it is difficult to overestimate.

The commission attempted to formulate some suggestions which might help to check this powerful drawback to the welfare of the colony and amongst other measures it recommended that, in order to help to lower the death-rate from sepsis in connexion with childbirth, more hospital accommodation should be provided for parturient women, especially married women. The commissioners also showed themselves alive to the important part which the care of the unborn will play in the future by recommending the establishment of pre-maternity hospitals where pregnant women could be taken in before their confinements and treated if necessary. Further recommendations included the compulsory notification of puerperal fever, which at present is not required in the colony, the licensing of lying-in homes and private hospitals, the more perfect administration of the Poisons Act, and the prohibition of the sale of preventives and of the indecent literature relating to their use. We fear, however, that such measures, although they will no doubt remedy existing evils, will not go far to remedy the deliberate prevention of pregnancy. The report rightly lays great stress on the part to be played by the strengthening of religious feelings. Upon this would follow the abolition of those motives of self-interest which at the present time have done so much to blind the people with regard to the immorality of such practices. It is only by the awakening of the higher sentiments of duty and self-control, sentiments which play so important a part in the development of the race, that any good is to be hoped for. The danger is one of imperial importance, it concerns not only the colonies but also the Mother country, and is one which becomes of increasing importance every year that it continues. Medical men can do much to assist and it is to their influence and to that of the teachers of religion that we look for help in the checking of customs which inevitably lead to decay of the social and moral qualities of the race and imperil in a very high degree the future well-being of the whole British nation.

The Amendment of the Workmen's Compensation Act (1897).

IT has for a long time been evident that the Workmen's Compensation Act (1897) is capable of improvement in several particulars and a departmental committee of inquiry was appointed to this end by the Home Secretary in November, 1903. The report of this committee was made in August, 1904, and its various recommendations included several which were open to serious objection. But, for the moment at any rate, we propose only to allude to those parts of the report which deal with the appointment of medical referees, this being, in our opinion, a matter of the first importance for the medical profession.

The Act of 1897 contains clauses providing for the performance of certain duties by medical referees but it is well known that these clauses have remained almost entirely inoperative owing to the services of the present medical referees not having been used by the county-court judges. A completely new suggestion is now made by the departmental committee. In Paragraph 265 of its report it is proposed that the medical referee shall be a "public official rather than a medical man in practice," and that he shall be remunerated not by fees but by salary. At first he might be allowed to combine the work of medical referee with some other public appointment, such as certifying factory surgeon or medical officer of health to a local authority, but the opinion of the committee is that the medical referees should eventually become part of the civil service. On the ground that the change partakes of the nature of an experiment it is recommended that only a limited number of such referees should be appointed and those only for a limited period, such as three years. In Paragraph 259 it is recommended that the reports of the medical advisers of the employers on the one hand and of the workmen on the other, if any, should be filed with the registrar of the county court, that the county-court judge should have a discretionary power as to ascertaining the opinion of the medical referee, and that a copy of the report of the medical referee should be accepted as conclusive evidence of the condition of the injured person at the time of the report. It is also suggested that the judge shall have power to summon the medical referee to sit in court as an assessor. Another important duty to be discharged by medical referees would be the giving of certificates as to the condition of aged, infirm, or maimed persons, and those certificates would presumably be "conclusive evidence." In framing these recommendations the members of the committee no doubt acted with the best possible intention, but they do not seem to have recognised fully the inherent difficulties of the medical questions involved or the extent of the departure from the existing system which incorporation of their proposals in an Act of Parliament would bring about. In the medical profession it is universally held that personal experience in the treatment of patients is essential to the formation of a sound opinion with regard to any given case, and in the application of a Compensation Act which necessarily presupposes divergence of opinion the weight of authority will usually be on the side of the most experienced witness. The departmental committee, however, oblivious of this cardinal principle, actually proposes that the referee of the future shall be a "public official rather than a medical man in practice" and would thereby prevent such appointments from being accepted by those who are the most competent to fill them. Under any Compensation Act conflicting opinions will have to be reckoned with, rebutting evidence will often be forthcoming, intricate questions of diagnosis must sometimes arise, and patients will occasionally present symptoms regarding which it may be very difficult to obtain "conclusive evidence." In fact, it requires no special faculty of discernment and no great familiarity with the methods of officialism to foresee that the recommendations of the departmental committee would tend to create a class of medical referees consisting either of (1) men willing to give their whole time on a three years' engagement, or (2) of medical officers of health who, being appointed solely to discharge administrative functions, have given up general medical practice, or (3) of certifying factory surgeons happening to have a practice so small that it is not worth retaining. We cannot regard any of these as ideal medical assessors under a Compensation Act.

We do not believe that the departmental committee could possibly have made these suggestions if there had been placed before it evidence of the importance of the offices which it was intended to create, to say nothing of the essential necessity of the medical referees or examining surgeons being men who would have the confidence of the medical practitioners in each district and whose opinions would be generally regarded as "conclusive." It would be intolerable if medical men of long experience in general practice or consultant surgeons of great special knowledge should have their opinions reviewed by officials of the status which is now foreshadowed. We notice also that, as in the Act of 1897, the county-court judges are to have the option of calling in the medical referees or not, and if the status of the medical referees is not unimpeachable it is easily to be seen that their services will not be required by the judges, when the amended Act, so far as the medical referees are concerned, will continue to be the dead letter that it is at present. We have long been of opinion that in the interests both of employer and employed the medical referees should decide all medical questions and that their decisions should be final, but the very fact of this finality, from which there is to be no appeal, makes the appointment of men of the highest professional knowledge and experience a *sine quâ non.* It will be our duty to watch the introduction of the Bill that is now being drafted and if it contains the recommendations of the departmental committee as to the appointment of medical referees, it will also be our duty to advise the medical profession to bring every possible influence to bear on Members of Parliament so that only men of position and experience may be appointed as judges over their *confrères.* It should be pointed out that with proper regulations and systematised arrangements by the court of the work of the medical referees the services of hospital surgeons could be obtained at certainly not larger expense than that of salaried officials—that is, if any reasonable or sufficient salaries are proposed to be paid. The question of the employment of experts, although mentioned in the evidence before the committee, is not touched upon in the report but will require consideration. If an employer or a workman has had the opinion of, say, a consulting ophthalmic surgeon, it would seem incongruous to remit that opinion to be revised by a medical man who had not given special attention to diseases of the eye. We think that the Secretary of State would do well, before passing the final draft of the amending Bill, to assure himself that any suggested rules for the appointment of medical referees would be likely to meet the views of medical men, as the success of the scheme is dependent on the absence of friction. The harmonious working of the medical referees with the medical men interested in the various cases is absolutely necessary unless the Act is to become a farce and we are sure that this can only be obtained by the appointment of medical referees of the highest standing with proper arrangements for due emolument, which implies mainly a due regard for the waste of the valuable time of busy men.

◆

The Public Appreciation of the Dangers and Treatment of Cancer.

MR. A. W. MAYO ROBSON, whose Bradshaw lecture before the Royal College of Surgeons of England was published in full in THE LANCET on Dec. 3rd, 1904, p. 1545, concluded his address by expressing the hope that some of the views that he had enunciated might filter through the medical profession to the public. In our columns a fortnight later we published a letter from Mr. C. HAMILTON WHITEFORD urging "the direct education of the public by the profession" in the earlier signs of cancer, when the need would become apparent for resort to operation early, if the best results are to be obtained from surgical treatment of this malady. All of us must oftentimes have seen cases of cancer where delay in resorting to an operation has seemed to have [illegible] of the case, and it not [illegible]ly to surgeons in such an advanced stage of malignant disease that cure by operation is wholly out of the question. It naturally occurs to us in the face of such tragedies to regret that the knowledge possessed by all operating surgeons had not been available to save the patients from such a calamity. But the question arises, What is the best way in which these disasters are to be prevented? And we are not prepared at once to adopt the position that the profession should take active measures to instruct the public in the signs and symptoms of the early stages of malignant disease in order that operative treatment may be obtained at the first possible moment. The risks of such a course are as obvious as they are real. A half-educated but wholly frightened public might try to force the hands of the general practitioner in junctures when the general practitioner would particularly require to be unembarrassed that he might face a difficult situation in a calm and unprejudiced manner. All those of the patient's relatives who had been educated, as they conceived, in the science of disease would at once take views on the possible or probable malignancy of the patient's condition. They might urge operation when the medical adviser deemed the course unnecessary or they might regard as an indication of innate bloodthirstiness his avowed intention of using the knife. In such circumstances the medical man's difficulties would be doubled and the patient would become the unconsulted spectator of a quarrel in the rights of which he might very well think that he was the chief person interested.

Let us also remember that to advocate education of the public in the dangers of neglected cancer is to imply that the public alone is at fault when the distressing situation occurs that patients die from malignant disease whose lives could have been saved if the condition had been detected in an earlier stage. We are not prepared so unreservedly to exonerate the medical profession from playing a part in the lamentable and admitted situation. Some cases of malignant disease come to surgeons at too advanced a stage for curative operation and the delay in resorting to surgery has sometimes been due to the failure of the medical adviser first consulted to appreciate the significance and gravity of the symptoms presented to him. In saying this we are not bringing a "railing accusation" against a large number of the medical practitioners of this country. We are well aware that there is something more that needs to be said on this subject. For many years now what are called "pre-cancerous diseases" have been described and in this respect there was absolutely nothing said in his recent Bradshaw lecture by Mr. MAYO ROBSON that has not been said before and often reiterated. Only our older readers can recall the time when Sir JAMES PAGET first described the disease of the nipple, which now bears his name, and described it too as a precursor of cancer of the breast; and many of us do not care to remember how many years it is since the various forms of chronic superficial glossitis were recognised as often ending in epithelioma of the tongue. The same is true of our knowledge of warts passing into cancer, of moles originating sarcoma, and of chronic mastitis terminating in cancer. Why has this knowledge been so slow in laying hold of the entire body of the medical profession? The answer to the question, we think, is this. Practitioners generally do know the facts, but they are often prevented from giving the soundest advice to their patients by two considerations. In the first place, with growing experience they see patients having these so-called pre-cancerous conditions living to a ripe old age without developing malignant disease, and the optimistic tendency is so strongly developed in many of us that what we have seen occasionally as a happy exception we are fain to take as a type of the commonplace and fairly expected event. Again, men of large experience have seen operations for cancer performed in the very earliest recognisable stage of the disease which have failed to relieve the patient entirely of his malady. We fear, from the way in which the question is sometimes discussed, that some surgeons encourage the thought that cancer is certainly curable by operation if only it be attacked in its early stages. There can be no doubt that the earlier any given case is treated and the more freely the suspicious tissue is excised the better the prospect of cure, but we do not think it is in accordance with known facts to say that, if only all cases of malignant disease were treated by the surgeon as soon as a diagnosis was satisfactorily arrived at, they would all be cured. It must not be forgotten that the malignancy is shown in more than one way. In some cases it is especially a local malignancy which may have many forms of expression, but in other cases the malignancy is chiefly expressed in an early infection of distant parts, while the local changes show but slight departure from benignancy. There is no doubt that the infection of internal organs by external cancers occurs at a most varying time in different cases, and the success of an operation for cancer depends not only upon the freedom with which the local affection is removed but also upon whether the operation anticipates internal infection. It must not be forgotten, too, that operations for malignant disease have of late years become more extensive than they were. This has been attended with a very considerable improvement in their results but we cannot doubt that the extent of operation has had influence in checking some members of the profession from recommending recourse to its assistance. We do not for a moment defend this position, but recognising the different ways in which the same facts are regarded by various minds we cannot help seeing that this also may be one reason why what is generally known appears not generally to be practised.

While we do not think that the public can be wholly blamed for reluctance to undergo operations upon grounds that must to some extent be speculative, and while we consider it unjust to reproach the medical profession —as is sometimes done—for the number of cases of cancer that reach the operating surgeon too late for operative interference, we think that the teachers of surgery must take their share of responsibility in the matter. They should be insistent upon the perils of delay and clear upon the duty of the medical practitioner to expect the worst in many circumstances where, after all, the happier issue may be the true one. The pre-cancerous states are seldom made the subject of much comment by teachers and do not suggest themselves as examination subjects. Lecturers, therefore, may be apt to omit the discussion of them with due stress, a fact which cannot be without its effect upon their pupils in the future exercise of their profession. We think that the medical profession, as a whole, should wake up to the fact that cancer is on the increase among us—at any rate, that many more cases can now be recognised than was possible formerly. But if the profession were to take upon itself the instruction of the public in the early signs and precedent conditions of all forms of malignant disease serious evil might follow. We all meet individuals who for many years of their life are overshadowed by a dread of the occurrence of cancer. Some have thought that this dread may in some occult way predispose to the attacks of the disease but, whether this is so or not, no one who has once witnessed the needless sufferings of an individual thus haunted would willingly risk the infliction upon a large number of the public of similar sufferings. Half-knowledge is a dangerous and distressing thing; in this matter the public would be at the best possessed with only half-knowledge. We think, therefore, that, at present at any rate, all that can be done is for the profession to consider thoughtfully the circumstances of the case. Practitioners must realise their great responsibilities; they must insist on all necessary examinations; they must, whenever possible, arrive at a diagnosis at the earliest moment; they must seek help in all cases where they feel difficulty in diagnosis or in treatment; and they must not shrink from advising operations in malignant disease, even where the signs of that disease are as yet but slightly marked, bearing in mind what must be meant by neglecting operation in malignant disease at the favourable time.

Annotations.

"Ne quid nimis."

THE RELATION OF THE LEISHMAN-DONOVAN BODY TO THE TRYPANOSOMA.

AT the time of the meeting of the British Medical Association at Oxford in July, 1904, the subject of the development of the Leishman-Donovan body had reached a very interesting point. Captain Leonard Rogers, I.M.S., had just announced by telegram from Calcutta that he had succeeded in developing trypanosomes from the Leishman-Donovan body. All those who heard this announcement and who were capable of grasping what it meant left the meeting anxiously looking for confirmation of the observation. At the present moment the state of belief may be summed up by saying that there is every probability that the observation is correct. Major W. B. Leishman, R.A.M.C., had already promulgated the idea that the parasite was probably allied to the flagellata and was directing his attention to the investigation of this belief. Other observers also were struck with several of the points of anatomical resemblance between the "body" and the trypanosoma, so that Captain Rogers's announcement fell upon minds ready to receive his conclusions. Since Sir P. Manson interpreted the significance of the crescent body in malaria bursting into flagella no more important scientific observation has been recorded, for the indications point not only to the "body" becoming a trypanosoma but the belief is entertained that the malaria parasites themselves may be but a phase in the development of these pathological occupants of the human blood. Dr. G. C. Chatterjee, with Captain Rogers's permission, has forwarded to us a paper on this subject with drawings of the trypanosoma cultivated in the laboratory from the Leishman-Donovan body. The paper is published at p. 16 of our present issue together with two plates, careful examination of which leaves little doubt as to the identity of the laboratory specimens of the parasite and those met with in the splenic blood of persons suffering from the obscure ailments caused by the presence of the parasite. The patient from whom Dr. Chatterjee obtained the specimens of blood on which his observations are founded is of particular interest, inasmuch as he came from Sylhet in Assam where kala-azar is prevalent. This puzzling ailment has long been a subject of discussion but there seems now to be but little doubt that the signs and symptoms and pathological changes characteristic of this disease are due to the Leishman-Donovan body. When the possible homology of these hitherto designated specific parasites and the apparently divergent diseases to which they give rise are contemplated the mind is directed towards a common origin for such diseases as malaria in all its intricacies, sleeping sickness, kala-azar, tropical cachexia, splenomegaly, and all the numerous undetermined febrile attacks and anomalous "continued fevers" with which the medical practitioner is familiar in hot climates. It would seem as though we were on the threshold of a great generalisation of primary pathological significance and of great scientific importance. The close bearing which the diseases of animals have upon those of man and *vice versâ* would seem to be carried a step forward by these recent discoveries. The trypanosomic diseases of animals here called nagana and surra, there called mal-de-caderas, and now horse and cattle sickness seem to have their counterpart in human beings. A parasite closely resembling the Leishman-Donovan body has been found in fish in Assam by Bentley in regions where kala-azar prevails, so that the inhabitants of the earth, air, and water seem to be linked together in their parasitic afflictions in a manner undreamt of but a few years ago. It is well known that plague attacks men and animals in common and it may be that many of the familiar diseases from which human beings suffer in temperate climates are "caught" from animals, especially domestic animals, to an extent which may tend to cause us to look upon pets of various kinds as dangers to health and to life.

THE REGISTRATION OF NURSES.

WHEN Parliament meets a few weeks hence the committee which is considering the subject of the State registration of nurses is expected to report the result of its deliberations. It is generally believed that the report will be adverse to the two Bills which at present hold the field, the proposals set out in the Bills being objected to rather than the principle of registration of nurses. It is recognised by many of those interested that some improvement of existing conditions is needed and should the proposals now put forward be condemned renewed efforts will be made to find some other means of dealing with the subject. But it is known that many members of the medical profession, from no narrow motives, but in honest belief that registration of nurses is not required, do not approve of either Bill, and the supporters of the Bills must recognise the features which render their proposals unacceptable if they wish to get anything like general medical approval. There are two features in the present proposals which are always sure to excite strong opposition and which might be eliminated without permanent harm to the movement for improving the training of nurses. The first is labour with a capital L and the second examination with a capital E. As regards the former there is no doubt that many influential persons are attracted to this movement by the promise that it gives of organising cooperation amongst an important class of women workers in order to prevent the exploitation of their labour by employers. Valuable as this step may be a proposal for registering nurses which carries with it a provision for forming any semblance of a nurses' trade union is doomed to fail in securing State recognition or even general support by the public. With respect to the second feature it may be noted that there is at present a strong revolt against the tyranny of examinations. The reorganisation of the University of London a few years ago was a direct result of this movement, which is also illustrated by Lord Curzon's action in abolishing many of the competitive examinations for posts in India and by the directions in Mr. Cecil Rhodes's will as to the method of selection of his Oxford scholars. It is therefore not to be wondered at that grave apprehensions are in the minds of many at a proposal to secure the proper training of nurses by setting up examinational tests. The ease with which the acquisition of facts from books can be tested and the difficulty of estimating so many of the qualities which go to make a good nurse lead some to regard with suspicion any sort of examination as a factor in a nurse's education. Certainly the idea of an examination conducted by examiners who have not taught the candidate, on the analogy of examinations for medical students in London, is undesirable as a test of the education of nurses. It would tend to superficial cram and would undoubtedly cause nurses to regard their all-important ward work as a mere means to an end. While any fear that this movement might be used to safeguard the interests of the employed against her employer can be eliminated by care in constituting the registration authority, so the evils of examination can be eliminated by care in deciding what shall be regarded as the qualification for registration. Certainly, so far as the great schools of nursing are concerned no more examination than is at present carried out in the schools themselves is necessary. The registration authority, however it may be constituted, would do enough if it set up an ideal curriculum as to length and general features and recognised all nursing schools willing to conform to the ideal, so that nurses who receive certificates of satisfactory training in these schools would be admitted to registration. It would, of course, be necessary to inspect the schools in the first instance and also to carry on a periodic system of inspection. The authority should, in fact, examine the schools and not the nurses, in which way, at any rate, so far as the nurses trained in the chief schools are concerned the dangers of examination could be avoided. We are sure that if the registration of nurses becomes a State duty it will be necessary to eliminate the evils of examination, but we are not so sure that the promoters of legislation in this direction understand the feeling of the medical profession or the public on the matter There are many who think that State registration, at any rate for the present, is unnecessary, and that a voluntary agency, erected by philanthropic effort, would meet the existing circumstances. Voluntary registration properly carried out would level up the education of nurses generally and would enable those nurses who have gone through a satisfactory training to secure some more public recognition of the fact than is provided at present by their hospital certificates.

SCURVY IN SOMALILAND.

IN a leading article in THE LANCET of Dec. 10th, 1904, p. 1659, we referred to some points in the etiology of scurvy. We have now received a reprint of an article in the *Indian Medical Gazette* (No. 7, July 7th, 1904), on "Scurvy in Somaliland; notes on the Condition of the Blood Serum," by Lieutenant F. A. Fleming Barnardo, I.M.S. Lieutenant Barnardo's observations were made with a view to determine the therapeutical value in scurvy of certain foodstuffs and drugs and also to try to elicit any information as to prophylaxis and treatment that might be of use in future campaigns. In the course of the investigation it was clearly shown that the essential feature in scurvy is a diminution of the alkalinity and coagulability of the blood. This fact had previously been demonstrated by Dr. A. E. Wright. Lieutenant Barnardo makes the plausible suggestion that the alimentary canal may be the seat of production of toxins in scurvy. That toxins evolved in the intestines do play an important part in many febrile conditions leading to blood destruction has been proved by the researches of Professor Ewald and others. Lieutenant Barnardo proceeds to argue that from the absence of any epidemic nature of scurvy and its inevitable onset after a dietary of insufficient alkaline foodstuffs it is certain that there is no new specific organism introduced into the system as in beri-beri. Probably the toxæmia, if toxæmia it be, is due to bacteria which are normally present in the alimentary canal but which have taken on an abnormally active development and formation of toxins consequent on the *diminished vitality* of the mucous membrane and a diminished bactericidal power of the tissues generally. In infectious and acute intoxications alkalinity of the blood is diminished, and as a condition of diminished alkalinity certainly predisposes to bacterial infection the disease is thus aggravated. These suggestions are certainly worth further consideration. If Lieutenant Barnardo's views are correct, indications for treatment are afforded which may prove to be of great value and the administration of intestinal antiseptics should be proceeded with. Lieutenant Barnardo utters a warning against the use of lime juice which has been kept in barrels. The juice of fresh limes, he says, is of value but he contends that the preparation which has been preserved for some time tends to decompose into carbonates and free citric acid and can then be of no avail.

CURRENT THEORIES OF THE HEREDITARY PROCESS.

THE first of a series of eight lectures on the subject of Theories of Heredity was given at University College, London, on Nov. 22nd by Professor W. F. R. Weldon, F.R.S., Linacre professor of anatomy at the University of Oxford. Starting from the standpoint that the study of generations of individuals showed, first, that the average character attained by most of the members of one generation was like the average character of the preceding generation—a generally constant though not universal rule in the phenomena of heredity; and, secondly, that average persons are descended from average parents and exceptional persons from exceptional parents, it was claimed that these formed the necessary data of the science. These were facts based on the study of human races, of plants, and of animals. There was no necessity for starting with biological hypotheses to describe and to classify these phenomena of heredity. But when an explanation was sought of the mechanism or *modus operandi* of heredity, one passed, he said, outside the domain of statistics and concrete facts and had to picture the invisible organic processes accompanying the growth and the reproduction of animals. Reproduction in unicellular animals was illustrated by a description, with diagrams and slides, of the process as it occurs in the stentor, one of the protozoa. The body of the stentor, which is of an elongated pyriform character, is not a homogeneous unit but shows differentiation of organs, such as a thick vibratile band of cilia in the oral region, a hard cuticle beset with small cilia externally and attached internally to a system of fine muscular fibrils, a long moniliform nucleus and three smaller micronuclei, a mouth, and a contractile vacuole or excretory organ, while the general cell protoplasm is finely granular in appearance and the ectoplasm forms a clear subcuticular layer. In the process of growth the "ectodermal" part produces more cuticle, cilia, clear protoplasmic layer, and myo-fibrils, and the granular protoplasm produces granular protoplasm—in fact, each part of the body exhibits increase of its special structure. The body of the stentor is, in fact, histologically differentiated. On section of the body transversely into two or three equal parts each part thus separated grows and regenerates itself into a complete stentor, the anterior or cephalic segment growing a body and foot portion, while the middle part regenerates both head and foot portions, and the third or foot portion regenerates body and head. Cut into slices half a millimetre thick, the cut slices regenerate, each into a complete stentor. A stentor is thus composed of "units" each of which, removed from the rest, is capable of rebuilding the whole body system of units. These units as they exist bonded together in the body must have many properties latent, but when, for example, the head region is cut off the neck region is roused from its latent or dormant state and regenerates a fresh head region. In the natural process of reproduction the stentor undergoes elongation and develops a constriction in the middle, the ciliated band, nucleus, and contractile vacuole each divides into two, and one each of these passes to the posterior half of the body which is then completely constricted off, each half or miniature stentor now rapidly growing into full size. There is thus a division and rearrangement of the bodily parts or "units" of the stentor preceding its reproduction by fission. Experiments made on all protozoa (except sporozoa which are impossible to experiment with) suggest similar facts and deductions of a general reaction essentially similar to the stentor. The stentor is asexual, concludes Professor Weldon, and the occasional meeting and adhesion of two individuals with partial exchange of material is necessary for their well-being (rejuvenescence), but this phenomenon has nothing to do with reproduction. In some protozoa after such partial union and exchange of material the separated organisms seem to exhibit increased power of reproduction. In hydra the phenomena of growth and regeneration are similar. Each tissue reproduces its kind and a thin section reproduces the whole body and tentacles. In hydra reproduction occurs in two ways or more, first by budding, in which a tubular finger-like projection of the body wall, or sometimes of the ectoderm alone, grows into a small hydra which eventually separates from the parent. The second method is the production of a large somatic cell (ovum) beneath the ectoderm. This gives rise to two polar bodies (*maturation phenomenon*), and after their extrusion the ovum is fit for impregnation. Other somatic cells of the hydra give rise by division into minute flagellate cells (spermatozoa) which are liberated. When these free-swimming elements meet the ovum one of them enters into and fuses with the latter (*fertilisation*). From the impregnated egg a young hydra arises by the usual process of embryogenesis.

THE TREATMENT OF EPILEPSY WHICH IS DUE TO TOXÆMIA.

Dr. Allan McLane Hamilton of New York has published an article in the *Medical Record* of New York of Dec. 3rd, 1904, embodying his own large experience in the treatment of those cases of epilepsy mainly due to conditions of toxæmia—auto- and hetero-toxæmia. The treatment of epilepsy from remote times has for the most part, says Dr. Hamilton, been empirical if we may except that of a surgical kind, while many drugs recommended for epilepsy have been "mere therapeutic guesswork" due to imperfect knowledge of its pathology. Putting aside those forms of epilepsy due to premature ossification of the cranial bones, to fœtal or infantile injury or disease of the brain, or to the growth of neoplasms, "there is a large number of so-called idiopathic cases which are exceedingly obscure, as it is impossible with any certainty to trace either a cause or underlying morbid process." These are the cases, he adds, which have been especially treated with bromides "with the idea of smothering the activity of the cellular elements in the brain." From a critical review of the work of Raymond and Petit, and especially of Voisin,[1] and from a consideration of the bio-chemical facts regarding the blood and urine of epileptics demonstrated by Herter and Smith, and later by Carlo Besta (1902) and other Italian investigators, it is rendered probable, says Dr. Hamilton, that toxæmia enters largely into the pathogeny of epilepsy. The occurrence of the fit betokens the accumulation in the body of some particular toxic agent in quantities sufficient to excite the cerebral nerve cells to convulsive discharge. The toxæmia was probably a mixed one—i.e., both autogenous and heterogenous. Eclamptic attacks and the functional epilepsy produced by absinthe drinking illustrated the action of toxæmia in the brain. Auto-toxæmia occurred in three ways: first, from gastro-intestinal derangement which set free purin bodies and putrefactive products (indican and skatol) in the alimentary canal to be taken up by the blood; secondly, the presence in the blood of certain familiar cocci, such as the staphylococcus aureus and albus; and thirdly, by poisoning of the cerebral nerve cells by degradation products of the nervous tissue, among such toxic products being cholin which was shown by Mott and Halliburton to be toxic to cats. Clinical study of the pulse shows a lowering of arterial tension before a fit, as was found in every one of 18 cases carefully investigated by Voisin and Petit. Such a soft pulse generally exhibited acceleration as well. "I have learned to look upon a soft rapid pulse," says Dr. Hamilton, "with considerable apprehension, for in many epileptic subjects its presence often precedes the development of an attack or series of attacks." The urine in these cases contains excess of indican. Among the therapeutic suggestions given by Dr. Hamilton are hydrotherapy, carbonic acid baths, friction, and massage to aid the elimination of waste products of metabolism by the bowels, the kidneys, and the skin. Meat, coffee, tea, and purin-containing substances should be practically excluded from the dietary. Calomel and boric acid are useful in aiding intestinal asepsis, while among the more valuable cerebral sedatives are chloral, the bromides, and veronal, the last of which should be given dissolved in hot water.

A PECULIAR FEATURE OF THE RECENT FOG.

DURING the time when the recent fog was densest on the ground a curious phenomenon was witnessed in THE LANCET offices and laboratory. The flames of the Bunsen burners attached to gas stoves, as well as of those used for laboratory purposes, which are normally of a bluish tinge, became a bright yellow colour, which on examination with a spectroscope proved to be due to sodium. The characteristic bright yellow colour of the flame was well marked and the usual soda line in the spectroscope was very brilliant. On examining the air no definite evidence either of sulphates or of chlorides could be obtained. The interesting questions are, What was the origin of the sodium and in what form did it exist? It is easy to imagine sea air showing the presence of sodium chloride but it is difficult to understand how under the conditions prevailing during the fog the air could contain particles of sea-water. It is true the fog was very general and possibly some of it had its origin in the sea but then no chlorides could be found in the air. Again, it may be conjectured that smoke might contain sodium salts derived from the combustion of coal but we find that sodium salts are seldom found in coal. We do not know, and have had no means of ascertaining, whether there was a local disturbance at any chemical works or other places where sodium salts are likely to predominate, these salts for some reason or other becoming scattered and thus giving rise to the curious flame phenomenon recorded. It was not due to our own laboratory operations, for the intense yellow colouration of the flame was evident in all parts of the offices and the colouration was just as intense on the lower floors as on the top floor, where the laboratory is situated.

LORD MOUNT STEPHEN'S MUNIFICENCE.

Lord Mount Stephen has for the second time made a princely donation to the King's Hospital Fund for London. It may be remembered that an anonymous donor recently offered to contribute capital producing £3800 per annum to the Fund if the public within a certain date would find capital to produce £10,200 per annum. The £14,000 per annum so raised would have brought the fixed income of the Fund up to £50,000 per annum. The anonymous offer, however, lapsed, the public having made no adequate response to the appeal issued by the Prince of Wales as President of the Fund. Lord Mount Stephen has now come to the rescue and has placed at the disposal of the Prince of Wales to be used for the Fund, bonds worth £200,000, producing £11,000 per annum, "leaving" as he says, only "£3000 a year still to be provided and affording a great opportunity for someone willing and able to do a beneficent act." Lord Mount Stephen's generosity is well known but he has never helped with his magnificently open hand a worthier object. The value of the Fund will be greatly increased by the possession of a fixed income of £50,000 and we can hardly doubt that the remaining £3000 necessary will be forthcoming.

HEREDITARY ANGIO-NEUROTIC ŒDEMA: ŒDEMA OF THE GLOTTIS IN FIVE MEMBERS OF A FAMILY.

WE have recently referred to a case of angio-neurotic œdema in which the larynx and stomach were affected and tracheotomy had to be performed.[1] At the meeting of the Société Médicale des Hôpitaux de Paris on Nov. 3rd M. E Apert and M. Delille described a remarkable case in which the disease occurred in a hereditary form and five members of a family suffered from œdema of the glottis. On Oct. 8th, 1903, a boy, aged nine years, was taken to hospital in a state of asphyxia with suprasternal and epigastric retraction. There was no sign of diphtheria but the whole of the soft palate and the uvula were transformed by œdema into a voluminous gelatinous-looking appendage which quivered, like the condition seen in acute œdema of the glottis in Bright's disease. There was an œdematous swelling of the sub-mental region. The dorsum of the right foot was white and swollen; the œdema was hard and pitted on pressure but only superficially and momentarily. There was no cardiac or renal disease. The heart was normal and there was no albuminuria. The nature of the œdema would have perhaps been doubtful for a long time if attention had not been attracted to the patient's uncle who accompanied the lad and was wearing a tube in his trachea. He stated that other members of the family were similarly affected. The patient's father and his two paternal uncles suffered from angio neurotic œdema as well as his only brother. On the other hand, his paternal aunt and his two sisters were not affected. A phenomenon sometimes observed in family diseases was illustrated. The disease appeared at an earlier age in the second generation. Thus the ages at which symptoms appeared in the first generation were 30, 28, and 20 years; in the second generation seven and five years. The patient had suffered from attacks of œdema which at first were rare, then became more frequent. The sites were variable—the upper limbs, the cheeks, and the forehead; more rarely the lower limbs. For the last four months whenever the face was affected swelling of the tongue and uvula followed and then obstructive dyspnœa indicating œdema of the glottis. Every fortnight almost exactly alternatively an attack of œdema of the limbs or of œdema of the face followed by œdema of the glottis occurred, the latter being usually accompanied, as in the patient's father, by pains in the stomach and nausea. When the boy was taken to hospital the temperature was 99·5° F.; in the evening it was 100·5°. On the following morning it was 103·2°, and the œdema of the glottis, uvula, and foot had disappeared; but there was a resistant swelling on the right cheek and a smaller one on the left side of the chin. On the third day there was no œdema of the cheek and the temperature was 99·1°. On the fourth day the boy was taken from hospital, having again a little œdema of the face. The hereditary transmission of angio-neurotic œdema is well recognised. Professor W. Osler has related an instance in which 22 out of 39 persons distributed in five generations were affected.

INJURIES DUE TO GYNÆCOLOGICAL EXAMINATIONS.

In the *Journal of the American Medical Association* of Nov. 26th, 1904, Dr. Howard A. Kelly has drawn attention to a subject which has received little notice—the infliction of injuries, particularly to the rectum, during gynæcological examination. The organ which is being examined or the structures which lie between it and the examining fingers may be injured. The injury may be due to the delicate nature of the tissues examined or to roughness in examination. A thin-walled papillary cyst, vascular cystic sarcoma of the ovary, an extra-uterine pregnancy, or a pelvic abscess may be ruptured into the peritoneal cavity. Small effusions of blood may be produced under the skin of the abdomen from bruising during examination. Dr. Kelly has never seen injuries of the vagina but he has seen four cases of perforation of the rectum which is a much more delicate structure. All occurred in his hospital practice during the last 15 years. The examiners were not inexperienced students but competent assistants and, in one case, himself. In the first case a married woman, aged 52 years, was placed under ether in order to be curetted for menorrhagia. During examination the finger was pushed through the rectum into the peritoneal cavity. An incision was at once made in the posterior fornix. A vertical rent was found in the rectum four centimetres above the cervix. It was closed with fine silk sutures and recovery followed. In the second case a married woman, aged 63 years, had cystitis. Under ether an examination of the pelvic organs was made and they were found to be normal. The finger was pushed through the rectum into Douglas's pouch. An operation was performed similar to that in the previous case and an iodoform gauze drain was brought out through the vagina. Recovery was complicated by a fæcal fistula which closed spontaneously. In the third case a woman, aged 58 years, had a large left ovarian cyst widely adherent to the intestines and the omentum. During examination, before the anæsthetic was given, Dr. Kelly pushed his finger through the rectum into the peritoneal cavity. The abdominal incision for ovariotomy was made, the tumour was removed, and the rectal tear was exposed and sutured. No soiling of the peritoneum was apparent and drainage was not used. Recovery was uneventful. In the fourth case the patient was a woman, aged 28 years, suffering from menorrhagia. She was anæsthetised for curetting. In the course of a rectal examination the finger was pushed into the peritoneal cavity. A piece of gauze was pushed through the opening and brought out at the anus. On the following day there were symptoms of peritonitis, therefore the abdomen was opened, the tear was sutured, and the pelvis was drained. Recovery slowly took place. Dr. Kelly thinks that the cause of these accidents was the age of the patients (in three averaging 57 years) and weakened muscular tone of the bowel. In one case the patient was very stout, so that not only was a greater effort required to reach deep structures in examination but the tissues were probably more friable. Dr. Kelly recommends that in all cases the peritoneum should be opened and the rent sutured from the peritoneal side. Two layers of fine silk sutures are better than one. An iodoform gauze drain should be inserted through the vaginal vault. The most convenient route is through the posterior fornix unless the abdomen is about to be opened, but if the perineum and the vagina are rigid and contracted an abdominal incision would be preferable. In either case the operator must be skilful in sewing at a distance with long instruments. The sutures should be well placed, penetrating the coats of the rectum as far as the mucosa, and accurate apposition should be secured. As a rule no food but albumin water should be given for from five to seven days. The anus should be thoroughly dilated and if a rectal tube can be tolerated it will serve to carry off the gases and to keep the parts at rest. In order to avoid such injuries rectal examinations should be made with the utmost gentleness. It is well to empty the bowel beforehand. If the patient is then placed in the genu-pectoral position and a speculum is introduced so as to secure a maximum of distension with air, on placing the patient in the dorsal position the rectum will be found expanded and in closer relation to the pelvic structures. An important point, not sufficiently emphasised, is that the examiner should avoid the natural impulse to invaginate the wall of the rectal ampulla on the finger and push it high in the pelvis. This error will not occur if, after introducing the finger into the ampulla, the next step is to seek the so-called "third sphincter"—the rectal valves behind the cervix. The finger should be introduced between these, then up into the pelvis where the bowel lies in contact with the posterior surface of the uterus and left broad ligament. The examiner should be at ease and the fingers should be flexible during the examination. If the whole arm is made rigid in the effort to push in the perineum in order to gain a few centimetres the hand is also apt to become rigid. Dr. Kelly avoids rigidity of the arm by resting his elbow against his hip and pushing in his arm from the hip.

JUVENILE TABES AND OTHER HEREDITARY SEQUELÆ OF SYPHILIS.

Cases of juvenile tabes are still very rare. After careful search Marburg of Vienna (1903) could only collect 34 cases. In the *Journal of Nervous and Mental Diseases* for December, 1904, Dr. J. Grinker, lecturer in neurology at the North-Western University Medical School, U.S.A., records a remarkable case the family history of which is also full of interest in regard to the hereditary aspects of nervous diseases. The patient's mother came of a long-lived family, free from nervous or mental disease in the ancestry. She enjoyed good health, was married at the age of 18 years, and had a son who was in perfect health and was now 38 years old. Her husband died 15 months after the marriage from a fever. The woman remained a widow for 12 years when she married again, at the age of 31 years, her first cousin, a young man who had contracted syphilis four years previously and who had been in indifferent health since then. He was mentally normal but drank to excess and died after 22 years of married life, probably from chronic tuberculosis, The issue of this unfortunate marriage, says Dr. Grinker, comprised three children whose conditions illustrate the various hereditary sequelæ of syphilis in a striking way. The eldest, a male, was born in May, 1878, and developed into a typical case of juvenile tabes dorsalis; the second, also a male, born in October, 1880, manifested general paralysis during adolescence; and the third, a female, showed signs of infantile cerebral syphilis soon after she was born in 1882. The woman not only brought forth these hereditarily degenerate children but in the course of years developed into a case (rare in women) of tabes dorsalis herself. Her illness began 12 years ago with numbness and tingling of the feet and a sensation as though she was walking on a "stuffed cushion." Then followed paræsthesiæ ("pins and needles" and dull sensations of pain) in the legs. "During the last ten years she had the classical lightning pains of tabes, which were mostly at night." For the past five years similar shooting pains had occurred in the upper extremities. Vision was gradually lost in the right eye and subsequently in the left eye, so that the patient became at length totally blind. For seven years she had had the abdominal pains or "crises" of tabes—"twisting and grinding of the stomach and intestines," as she described them. Gastric crises with vomiting and intense agonising pain in the epigastrium lasting from 12 to 24 hours were also experienced. At present (1903), says Dr. Grinker, she is "a small, poorly nourished old lady of apparently 65 or 70 years, though her real age is 57." She is the subject of chronic locomotor ataxy, with absent knee-jerks, ataxia of station and of gait, and numerous peripheral areas of cutaneous analgesia. Complete optic atrophy is present. Intelligence and memory are good. The sphincters are beginning to show slight incontinence. The lightning pains, Westphal and Romberg symptoms, optic atrophy, gastric crises, paræsthesiæ, and absence of motor involvement make this an undoubted case of tabes dorsalis, while the children of the woman illustrate various pathogenic aspects hereditarily transmitted. This patient died in April, 1904, from coma.

THE medical officer of health of the Cape Colony states that for the week ending Dec. 10th, 1904, the condition of plague in the colony was as follows. At Port Elizabeth 2 cases were discovered during the week, both being of European females. Of 153 rodents bacteriologically examined 4 rats and 11 mice were found to be plague-infected. Plague-infected rodents continued to be found in East London. Elsewhere in the colony no plague infection in man or other animals was noted. As regards the Mauritius a telegram from the Governor to Mr. Lyttelton received at the Colonial Office on Dec. 30th states that for the week ending Dec. 29th there were 19 cases of plague and 11 deaths from the disease.

THE opening lecture of the spring session of the North-East London Post-Graduate College will be given at the Tottenham Hospital, N., on Jan. 10th, at 4.30 P.M., by Mr. John Langton, consulting surgeon to the hospital and to St. Bartholomew's Hospital. The subject of the lecture, which is open to all medical practitioners, is "Points which should be considered in Determining the Prospects of the Operation for the Radical Cure of Hernia."

Major Robert Bird, I.M.S., surgeon to His Excellency the Viceroy and Governor-General of India, has been appointed a Companion of the Most Eminent Order of the Indian Empire.

OUR Special Sanitary Commissioner, who recently visited the St. Louis Exhibition, took the opportunity while in the neighbouring State to investigate thoroughly the famous Chicago stockyards and the condition of the celebrated abattoirs. It will be seen that our representative, speaking from a wide experience of such matters in all countries, was not favourably impressed with the sanitary regulations in force for the slaughter of the animals.

THE annual dinner of the Laryngological Society of London will take place at the Imperial Restaurant, Regent-street, London, W., on Friday, Jan. 13th, at 7.30 for 8 P.M.

Mr. W. H. Cross, who has retired from the post of clerk of St. Bartholomew's Hospital after 38 years' service, has been placed upon the commission of the peace for Middlesex.

MALINGERY.

THE art of shamming disease has reached a high level of perfection. This is mainly to be attributed to the fact that the rewards of proficiency are great. Fresh in the minds of all is the recent case of a professional beggar in the City of London whose voluntarily paretic limbs stirred up the lively compassion of the passers-by, even of the poor, so that charitable gifts flowed into his ready palm. This case has excited some little attention chiefly because the police have prosecuted him successfully but he is only one of very many. So remunerative are these attempts on the charity of the benevolent that there is great danger that the publication of the details of the case that we have mentioned will rather induce others to follow his example than that his punishment will act as a deterrent. In one part of London it is said that ready-made ulcers on pieces of adhesive plaster can be obtained at a reasonable price and these are greatly in vogue with professional mendicants, for an outward and visible sign, such as an obvious ulcer, is far more efficacious in exciting the almsgiving propensities of the tender-hearted than any amount of internal pains. Paralysis, too, is a fairly good argument in favour of charitable assistance, for the giver contrasts his powers of movement with the weakness of the afflicted one, and as paralysis of a kind is readily counterfeited it is much in favour with the begging fraternity, though a great deal of of it will not stand a careful medical examination.

Many are the motives which incite a man to pretend to be suffering from a disease with which he is not afflicted. Probably the commonest motive is the wish to obtain contributions from the charitable and thus to prevent the necessity for working which is extremely distasteful to these professional beggars. Ulcers and paralysis are the usual forms in which this motive manifests itself and to these we have already alluded. Fits of all kinds are, however, frequently simulated, especially fits of an epileptiform nature, and in cases where the malingerer has had opportunities of observing someone afflicted with epilepsy the resemblance to the true epileptic seizure may be extraordinarily great; the frothing of the mouth is usually brought about by means of a small piece of soap, the discovery of which in a "patient's" mouth would, to say the least, cause the fits to be looked upon with grave suspicion The fits are usually also rather overdone and it is a common failing of the malingerer that he is not satisfied with a reasonable amount of disease. Another motive nowadays for simulating disease is to obtain admission into a hospital. The comfort, the rest, and the luxuries to be obtained in hospital make a deep impression on many patients, so that they leave with regret to return to their former work. Can we wonder, then, that some of them, lamenting the fleshpots of Egypt, should wish to return? All that is necessary is to possess some severe manifestations of disease and every resident medical officer of a hospital must have met with many cases of patients endeavouring to obtain admittance on account of some wonderful pain or spasm and doubtlessly many a time has he been deceived. This form of malingering is especially likely to be successful when there is some obvious lesion which may form a basis for the superstructure derived from the patient's imagination. In one case a young man a few years ago received a severe blow on the head and even now some irregularity can be detected on the skull. He describes attacks of Jacksonian epilepsy and as the lesion is situated over the motor area of the corresponding side of the body he readily gains admission into a surgical ward. He will even agree to have an operation performed for the removal of the damaged portion of the cranial bone which is supposed to be causing his fits, though curiously he never has a satisfactory fit except when alone. His custom is to decline the operation when the day fixed for its performance arrives and on leaving the hospital he attempts, generally successfully, to repeat the performance elsewhere. One of the most inveterate of these malingerers is, or rather was, a man who had a genuine paralysis of the left arm with some weakness of the leg on the same side. He had tasted the delights of hospital life and as nearly every sojourn in the hospital was followed by two or three weeks at a convalescent home in the country or at the seaside he had an extra inducement to endeavour to be readmitted into a hospital. It was his custom when he felt inclined for hospital treatment to enter a tavern not far from a hospital. Here after a short time he would be seized with a "fit," and then he would be carried in an apparently unconscious or semiconscious state into the receiving room of the neighbouring hospital. The house surgeon would immediately detect the unilateral paralysis and would not unnaturally diagnose cerebral hæmorrhage or some other sudden interference with the circulation of the brain. The patient would be admitted at once and in a few weeks part of the paralysis would pass off leaving, however, some definite permanent loss of power, especially in the arm. Then would follow the convalescent home and later a return to the hard outer world where the unpleasant necessity of working would tend to obtrude itself on his mind. Then would come a visit, similarly inaugurated, to another hospital, with the same cycle of events. The number of hospitals in London being limited, it happened more than once that he returned to a hospital before the remembrance of his previous visit had quite died away. Some former clinical clerk who had become a house physician remembered his face or his history, which conscientiously he never varied, and then his well-planned enterprise was liable to come to a sudden and untimely end.

It is, however, in connexion with the naval and military services that the art of malingery finds its chief exponents. Indeed, the word "malinger" was first applied to the attempts of soldiers to evade arduous or unpleasant duty. It is of interest to notice the difference that exists between countries in which conscription prevails and those in which only voluntary service exists. In the former the most strenuous exertions are sometimes made to escape service and since most deformities disqualify for admission recruits, or rather those who were liable to serve in the army, have not hesitated to inflict on themselves the most severe injuries in order to avoid service. In the days when it was necessary for a soldier to bite off the end of the cartridge in loading his musket it was no uncommon event for a man to have one or more teeth extracted or filed down so as to obtain exemption. In countries such as our own at the present time, where voluntary service exists, we are more likely to find applicants for enlistment who attempt to hide diseases. In all countries, however, many soldiers, whether they have been called to the service by conscription or have entered it voluntarily, earnestly desire to leave it. There is an old tale, in all probability true, that illustrates well the trouble which such a man will take to escape from military service. A soldier was seized with paralysis of the right arm; the loss of power came on suddenly and without obvious cause. Malingering was suspected but all the efforts of the surgeon of the regiment were unavailing; no proof could be obtained that the paralysis was feigned. The man was examined by two medical boards and ultimately he was given his discharge. As he went off from the barracks on the top of the coach (it was in the days before railways) he waved a hearty good-bye to his comrades with his paralysed arm. Probably the best example of the perseverance which men will display in the attempt to leave a service which they detest is to be found in a case under the care of Cline. The patient was a sailor in the British Navy and it is worthy of note that he was a "pressed" man. He fell on to his head and a slight depression of the skull was produced. He immediately became unconscious and all efforts to rouse him failed. He lay quietly in his hammock and never moved. He seemed deaf to all sounds and at no time uttered any word. He was able to swallow food, both solid and liquid, and indeed he made signs with his lips and tongue when he wanted nourishment. He was brought back to England but no improvement followed and the "unconsciousness" lasted for 13 months. Then it was resolved to raise the depressed portion of bone. Flaps were made, a trephine was applied, and the bone was cut through. An elevator was then introduced to raise the bone and as the bone was lifted up consciousness suddenly returned to the patient and he spoke. At the time of the operation most of the onlookers accepted the case as genuine but no one would nowadays venture to support the idea that the patient really lay unconscious for 13 months, suddenly regaining consciousness on removal of the depressed bone. There can be no doubt that the man was a malingerer and adopted this arduous method of leaving a service into which he had been forced. The amount of pain and discomfort which malingerers are willing to endure to obtain their discharge is almost incredible but the facts are well attested. A limb has been held in a fixed position for many months and not even the application of the actual cautery has sufficed to move it. Many men have chopped off some fingers and have claimed that it was an accident. Mental derangement of one sort or another is a favourite form of malingery but the results usually resemble the popular or stage idea of insanity rather than the true products of mental alienation. It is not uncommon for the malingerer to combine two forms of insanity and this may be of value in detection. Still, it is often very difficult to be certain that a patient is shamming. There are, however, some phenomena which cannot be simulated. It is impossible for a sane man to imitate successfully the persistent insomnia which often occurs in the insane; the impostor cannot put off sleep beyond the second or third day.

Another frequent motive for malingering is to attract attention not for the purpose of obtaining money but merely to gain notice. This motive is most frequently seen in young unmarried women. The most common manifestation is to be found in the skin, where ulcers, bullæ, and other lesions suddenly appear. Simulated joint affections are also not rare and there are many other forms. These cases merge imperceptibly into hysteria and indeed in many hysteria is combined with the wish to deceive. It is not improbable that in some of these patients there is a certain degree of cutaneous anæsthesia which renders the self-mutilation more easy of accomplishment. There are other causes for simulating disease or injury. Sometimes it is done to avoid punishment, sometimes to wreak vengeance on another person who is accused of having inflicted the injury. To obtain compensation for injury in a railway accident several lesions may be simulated and especially those obscure and ill-defined conditions which have been attributed to "spinal concussion." These latter form a large and very important class the detection of the fraud of which is often most difficult. Sad to relate, many of the attempts to imitate disease have led to serious and irreparable results and even to death itself. A man excited an ulcer in his leg by means of a copper coin and later gangrene appeared and required amputation below the knee In endeavouring to excite hæmoptysis a man swallowed a cork into which pins had been inserted. He spat up blood and became very emaciated and then suddenly died from hæmorrhage. At the necropsy it was found that the cork and pins had lodged at the junction of the pharynx and œsophagus and that the pins had ulcerated through the œsophageal walls and had opened into the common carotid artery on both sides. Children are great adepts at feigning maladies and they frequently display a surprising acquaintance with the symptoms of disease. A little boy, five years old, complained that his urine was bright red, and so indeed it was, but it was found to be due, not to any blood colouring matter but to the red dye of his flannel shirt, a portion of which he had soaked in it. In another case a little girl vomited fæcal matter and this symptom only ceased when she was told that such methods were not allowed in the hospital.

The detection of malingering is often no easy matter and no general rule can be laid down which will be applicable to all cases. The mere threatening of severe methods of treatment is sometimes successful but frequently fails. The threat of the application of the actual cautery has cured paralysis but cases have been recorded where malingerers have endured the cautery on several occasions. A man who *simulated blindness was placed on the edge of a jetty* and told to walk straight forward. He stepped out and fell into the water, for he knew that those who were testing him dared not let him drown. In another case, however, a man who seemed to have paralysis of an arm allowed the amputating knife to be placed close to it without flinching but when thrown into the river he struck out with both arms and swam. A very useful method of detection is the suggesting of new signs and symptoms to the patient. The surgeon remarks—say in the case of a paralysed arm—in the hearing of the malingerer that it is strange that the little finger is flexed, it *ought to be straight*. In all probability at the next visit the little finger will have assumed the suggested position. The more *outré* and irregular the fresh symptoms suggested by the surgeon the more definite is the detection. In general anæsthesia we possess a valuable means of discriminating in certain cases between true and false paralysis or contractures. While the patient is just going under or recovering from anæsthesia the "paralysed" limb may be seen to move freely. It is well always to remember the possibility of a disorder being feigned, especially when a strong motive exists, for by this vigilance cases may be detected which would otherwise escape notice. In the detection, however, of cases which we imagine to be examples of malingery it is important that no methods should be adopted which can do harm, should our supposition be groundless, for it is far better that many impostors should succeed than that one real sufferer should be condemned uselessly to undergo further pain. It is no more than a mistake to be deceived by a malingerer, it is almost a crime to deal harshly with one who is really afflicted with disease.

ASYLUM REPORTS.

London County Asylum, Hanwell (Report for the year ending March 31st, 1904).—The average number of patients resident during the year was 2555, comprising 998 males and 1557 females. The admissions during the year amounted to 614—viz., 265 males and 349 females. Of these 518 were first admissions. Dr. R. R. Alexander, the medical superintendent, states in his report that the three chief causes which operated in the production of insanity among the admissions were alcoholic intemperance (21 per cent. of males and 12 per cent. of females), heredity (19 per cent. of males and 23 per cent. of females), and previous attacks (12 per cent. of males and 23 per cent. of females). 17 per cent. of the men and 2·5 per cent. of the woman were afflicted with general paralysis, as against 18 per cent. and 3 per cent. respectively in 1902. The number of cases discharged as recovered during the year amounted to 209—viz., 90 males and 119 females, or 8·2 per cent. of the average number resident. The deaths during the year amounted to 258, or 10·1 per cent. as calculated on the same basis. Of the deaths eight each were due to colitis and renal disease, 18 each to pneumonia and cancer, 20 each to cardiac disease and cerebral softening, 39 to senile decay, 39 to pulmonary and other forms of tuberculosis, 47 to general paralysis, and the rest to other causes. "The most remarkable feature of the general health of the asylum was the unprecedentedly high death-rate during the first quarter of the year. In that period we had 99 deaths (42 males and 57 females), or 38 per cent. of the total number of deaths of the year. ..... I am quite unable," adds Dr. Alexander, "to account for this death wave. It may have been partly owing to an irregular form of influenza, as we then had some undoubted cases of that disease ...... but most of the deaths had no apparent relationship to influenza and there was certainly no inclemency of the weather to account for the high mortality." The deaths included 33 patients (12 males and 21 females) over the age of 70 years. It is gratifying to add that a decline has been observed to occur in the mortality-rate of [illegible] sioners in Lu[illegible] and there is [illegible] rainfall of the year 1903 and the incapacity of the drains to carry off the *suddenly produced and torrential volumes of* rain water on May 30th and July 18th, two of the female wards were submerged. The flood invaded the female infirmary ward No. 7 to the depth of about 18 inches. All the patients (45 in number) had to be carried into other *wards and retained there until the* damage to the floor was repaired. The flood caused considerable damage also to other parts of the asylum. The committee of management states in its report that further measures have been taken to secure the safety of the inmates in the event of an outbreak of fire, including the provision of alternative exits for five female and four male wards, the formation of an additional fire station on each side of the asylum, and improvements in the fire-alarm system. Improvements in the boiler plant have been made and the cost of repairs, alterations, and improvements has amounted to £6982.

COCOA CHEMICALLY AND PHYSIOLOGICALLY CONSIDERED.

I.

ALTHOUGH cocoa was introduced into this country some five centuries ago and several years before either tea or coffee was known, it enjoyed but little popularity until comparatively recent days. It is an important fact, however, that cocoa is now in very great demand and official returns show that its consumption has increased enormously in this country in particular, the demand for it having given rise to a very considerable expansion of trade. There must, however, be some more special reason for this selection of cocoa as a beverage than can be explained by mere commercial enterprise. The present popularity of cocoa as a beverage and the fact that so many give it preference to tea and coffee raise some important physiological questions which claim more attention than they have hitherto received.

All three beverages—tea, coffee, and cocoa—contain well-known and well-defined stimulating principles, but there are marked and important differences of chemical composition between the three substances as might be expected considering that coffee and cocoa have their origin in the seeds of a plant while tea consists of a leaf. Moreover, all these undergo considerable modification during their manufacture. Coffee is roasted, tea is fermented and dried, and cocoa goes through a process of fermentation and roasting, and besides is submitted to a further treatment by which a considerable quantity of its fat is expressed. Thus the development of the flavour and the peculiar character of coffee is brought about by merely roasting, but in tea and cocoa both a fermentative process and a species of roasting are employed to the same end. These processes, though directed chiefly to the development of æsthetic qualities, are, of course, not without effect upon the chemical composition of the product and this effect has probably a dietetic significance. In coffee there are a loss of caffeine, the stimulating alkaloid, and a development of oil; in tea there is reason *for believing that the tannin or astringent* principles are rendered less soluble by the fermentative process (green tea is not fermented and yields much more tannin than does black tea); and in cocoa the initial bitterness of the bean is considerably reduced and its colouring is deepened, while roasting the cocoa according to the degree to which the process is carried intensifies the colour still more, and develops at the same time an oil of pleasing character much in the same way as does roasting coffee. In cocoa also some of the tannin is apparently changed into a colouring matter termed "cocoa red." Even in their original form, however, the proportion of theine and tannin differs widely in tea, coffee, and cocoa, and it is improbable that the tannin in the finished products is identical in kind. The tannins are a very numerous class of bodies, varying widely in character, and it is probable that coffee, tea, and cocoa contain each a different tannin or astringent principle, presenting not only different chemical but different physiological characteristics also. Tea certainly gives the most powerful astringent infusion, coffee coming next, while cocoa appears to possess quite a feeble astringency. It may be easily surmised that it is to this latter property that cocoa owes its negative effect upon digestive functions. Tea contains 10 per cent. and upwards of tannin, and coffee and cocoa contain 4 per cent. As regards their content of alkaloid, tea yields from 3 to 4 per cent. of caffeine, coffee 1 per cent., and cocoa about 2 per cent. of theobromine, an alkaloid closely allied to caffeine.

Apart from these considerations cocoa is consumed not in the form of a clear liquid, as are both tea and coffee, but in the form of an infusion containing in suspension, in a more or less finely divided state according to the particular mode of its manufacture, the whole of the cocoa. In other words, while the teaspoonful of tea or the teaspoonful of coffee is not entirely represented in the cup the teaspoonful of cocoa is. The cupful of tea or coffee infusion represents but a fraction of the tea or coffee used; the cupful of cocoa contains the whole of the cocoa used. On the one hand is a clear infusion, on the other an emulsion or infusion containing suspended matters in a more or less finely divided state. Whatever differences exist therefore between tea, coffee, and cocoa, the last, by the manner in which it is employed in making a beverage, must necessarily be more economical in use. This is a point of some importance which must be considered when making a comparison between the chemical composition and the dietetic value of the three products. Tea and coffee may thus be said to resemble meat extracts containing merely the stimulating principles of the prime substance while cocoa may be placed on the footing of the meat itself assuming that cocoa contains food materials. As a matter of fact, recent experiments on the behaviour of cocoa under the influence of digestive ferments have convinced us that cocoa is *per se* a valuable food yielding on digestion hydrolysed products which are available for the repair of the waste of the body. We shall return, however, to this point in a future number when our experiments are concluded.

A good preparation of cocoa is often recommended where tea and coffee have been shown to disagree and a great proportion of the public has been led to abandon tea and coffee in favour of cocoa, probably for a sound physiological reason. Leaving out all question of the pernicious habit of excessive tea or coffee drinking it remains to consider why it is that cocoa often is suitable when tea or coffee disagrees. As regards influence on digestion it is, at any rate, fairly well established that cocoa does not affect unfavourably either salivary or gastric digestion, and while tea and coffee reduce the absorbing capabilities of foods (probably by the hardening action of the astringent principles on the proteids) cocoa actually increases this power. Chemically, therefore, there may be tannin in cocoa but physiologically it behaves as though it had lost its astringent property. It would appear, therefore, that cocoa, far from being harmful, may be beneficial in acid dyspepsia. The observation has, in fact, been made that cocoa is tolerated and is even of advantage in enfeebled digestive power when tea and coffee set up serious interference with the digestive process. Again, the action of cocoa on the nervous system is very much less than that of tea or coffee. Cocoa differs in one very marked particular from tea and coffee in that it contains a very high proportion of fat. In raw cocoa this fat amounts to about 50 per cent.; in the manufactured article it is about 30 per cent. In spite of its low melting point—a characteristic which, as a rule, is in favour of the digestibility of a fat—cocoa fat has been asserted to be difficult of digestion. Distinct proof of this appears to be wanting and it is probable at any rate that cocoa fat is very readily emulsified and split up by the action of the pancreatic juice. One way of reducing the proportion of fat in cocoa has consisted in mixing starch with the cocoa—a proceeding which obviously attenuates the cocoa and whatever dietetic value it may possess is thus considerably diminished.

We may next turn to the approximate composition of the cocoas on the market. Excepting those cocoas which are admittedly mixed with substances foreign to cocoa itself the cocoas of the leading firms exhibit according to our analysis the following ranges in composition.

TABLE I.

Moisture	3·0 to	8·0	per cent.
Nitrogenous matter (N × 6·3)	19·0 ,,	20·0	,,
Fat	26·0 ,,	31·0	,,
Mineral matter (ash)	3·9 ,,	8 8	,,
Starch	2 7 ,,	7·3	,,
Cellulose	6 8 ,,	7·2	,,
Other non-nitrogenous matters	29·0 ,,	31·0	,,
Theobromine	1·7 ,,	2·0	,,

There are slight variations in the percentage of moisture which affect not very materially the proportion of the other ingredients. The variation in the percentage amount of mineral matter is in some cases considerable and this depends upon the method adopted in the manufacture of the cocoa. The preparation of cocoa from the raw material is a comparatively simple operation. It is roasted, ground, and the fat is pressed out while hot. The pressed cocoas are then finely ground. The degree of fineness to which the cocoa is ground is a matter of considerable dietetic importance as will appear from further experiments which we shall record. Cocoa so prepared commonly exhibits an acid reaction and has a tendency to deposit more or less rapidly a considerable sediment in the cup. Cocoa is not, strictly speaking, soluble in water; but by certain processes of manufacture it can be reduced to a largely soluble state by first of all grinding it exceedingly fine and then by increasing the proportion of its natural salts. Such cocoa is not acid to test paper owing to the neutralising action of the alkaline organic salts and yields practically no sediment in the cup, the exceedingly fine particles being in a state of perfect suspension, a condition which is assisted by the salts. This important modification in the method of preparation accounts for the variations in the amount of mineral salts found in the various commercial cocoas. There are thus practically two classes of cocoa in the English market—one which is simply roasted, ground, and the fat expressed, and another in which in addition to the above the natural salts are increased in order to raise the true solubility of the cocoa.

It has been freely stated that some cocoas in the English market are largely manipulated with alkali. Our experience gives no support whatever to such a statement. On the contrary, of 11 cocoas purchased in the open market we have not found a single one to contain anything in the nature of an alkali. They were either acid in reaction or perfectly neutral as regards alkali. By alkali we mean either the carbonates or hydrates (caustic) of the so-called alkaline metals (potassium and sodium). Moreover, in no instance was the slightest trace of soap found, formed by the action of alkali on the cocoa fat. The charge of using alkalies in the preparation of cocoas has chiefly been made against the Dutch manufacturers and there are some very excellent cocoas sold in this country which are manufactured in Holland. We give below a list of the cocoas which we have examined and the results of their analysis as regards the question of alkali in the cocoa itself, total mineral matter, and the alkalinity of the ash.

TABLE II.

Cocoa.	Total mineral matter (ash). Per cent.	Alkalinity of ash reckoned as potash. Per cent.	Alkali in cocoa.
Bensdorp's Soluble (II.)	7·10 ...	2·35 ...	None.[1]
Barry's Essence (I.)...	4·60 ...	1·08 ...	,, [2]
Van Houten's Soluble Cocoa (II.) ...	8·80 ...	3·14 ...	,, [3]
Epps's Cocoa Essence (I.)	3·90 ...	0·75 ...	,, [4]
Fry's Concentrated Cocoa (I.) ...	5·50 ...	1·97 ...	,, [5]
Cadbury's Cocoa Essence (I.)... ...	4·00 ...	0·65 ...	,, [6]
Mazawattee Cocoa (II.)	5·50 ...	2·06 ...	,, [7]
Schweitzer's Cocoatina (II.)	5·70 ...	2·02 ...	,, [8]
Suchard's Soluble Cocoa (II.)... ...	6·40 ...	3·55 ...	,, [9]
Rowntree's Elect Cocoa (II.)	7·40 ...	3·14 ...	,, [10]
Loose Cocoa (II.)	7·70 ...	2·96 ...	,, [11]

[1] Slightly alkaline potassium salts, but neutral as regards free alkali. [2] Slightly acid reaction. [3] Slightly alkaline reaction due not to alkali but to organic salts of potassium and phosphates; otherwise perfectly neutral. [4] Acid reaction. [5] Acid reaction. [6] Acid reaction. [7] Neutral reaction. [8] Neutral reaction. [9] Neutral. [10] Neutral, rich in organic salts of potassium, including phosphates. [11] Neutral, rich in organic salts of potassium, including phosphates.

The Roman numerals in parentheses indicate the class to which the cocoa belongs.

Certainly as regards the well-known manufacturers of cocoa which is sold in this country, whether English or Dutch, there is here no evidence whatever of the use of alkalies in the preparation of the cocoa. There is abundant evidence, on the other hand, showing that the natural organic salts of the cocoa have been materially increased as regards both some of the English and the Dutch manufactured cocoas. These salts are converted into carbonate on incineration. The natural salts of cocoa consist of tartrates, malates, or citrates of potassium, which all give a slightly alkaline reaction and carbonate of potash on ignition. Besides these salts there is invariably present also the important alkaline salt potassium phosphate. Of such cocoas (Class II. in the second of the tables) it would be just as true to say that they contain alkali as it would be of wood because on burning it yields potash or potassium carbonate in the ash.' Again, tea yields a strongly alkaline ash due to potassium carbonate derived from the organic potassium salts in the leaf but it would be obviously absurd to conclude that *potash or alkali exists as such in tea; in fact,* all vegetable matter more or less contains organic salts of potassium which decompose into the alkaline carbonates found in the ash. While we are able to state that the cocoas sold by well-known manufacturers in this country do not as a rule contain alkali, we are aware that alkali (ammonia, soda, and potash) is sometimes employed for the purpose and that this is especially the case with cocoas of German manufacture chiefly sold in Germany.

In a future number we propose to give some experimental evidence which we have been able to obtain bearing upon the food value of cocoa and particularly upon the digestibility of its constituents as determined in experiments *in vitro* with digestive ferments. We may add that the indications so far are in favour of pure cocoa being a valuable and complete food, although it must be borne in mind that the quantity of cocoa contained in a cupful of cocoa is obviously small.

(To be concluded.)

Looking Back.

FROM

THE LANCET, *SATURDAY,* Jan. 6, 1827.

HÔPITAL ST. LOUIS.[1]

This Hospital, which was built during the reign of Henry IV., owes its origin to the prevalence of some fatal disease which reigned in Paris in 1606, and was supposed to be contagious; the Hotel Dieu, at that time the only public hospital, was so incommodious and badly managed, that it served only to accelerate the death of the unfortunates sent into it. St. Louis, at the time of its construction, was at a distance from any populous quarter of the city, and to prevent more effectually the spread of the supposed contagion, the architect surrounded it with a court 100 feet wide, enclosed within double walls. The hospital forms a parallelogram of 360 yards by 240, and thus presents a superficies of 259,200 feet. The principal buildings are situated around an area of 300 feet square toward the centre of the enclosure, and are two stories high; the attics of the building are large, but unemployed.

This hospital contains 1100 beds, and is destined principally to diseases of the skin. Some surgical and epileptical cases are admitted, but the number of beds occupied by these patients seldom amounts to more than 160.

The principal medical officers are Alibert and Biett, and the principal surgical, Richerand and Jules Cloquet.

Dr. Gales, who was formerly apothecary to the hospital, imagined that he had discovered animalculæ in the vesicles of the itch; he contrived to convince Latraille of their existence, as well as the greatest part of the members of the committee appointed by the Academy of Sciences. In the Dictionary of the Medical Sciences, (Art. *Gale.*) there are engravings given of these insects, which are dignified with a peculiar order and genus. . . . . . . Many of the ancients considered that the proximate cause of the itch was the presence of an animalcula between the epidermis and skin. Redi, an Italian, described some insects which he thought he had seen in the itch pustules, as early as 1685; the same assertion has been repeatedly made by Fabricius Hildanus, Gaubius, and Morgagni, but the subject was almost unknown to the public, until Dr. Gales renewed the investigation, and declared that he had seen these beings in thirty-five patients at St. Louis. He engaged a celebrated draughtsman to copy some of them, and these were afterwards shown to the academy; a committee was appointed to examine into the matter, and they agreed in saying that they also had seen them. Latraille in his Genera Crustaceorum, and, indeed, most entomologists since his time, have named them *sarcoptes scabiei*, and placed them with the family of the *acari*. Linneus has placed them in the class aptera, and has called them *acari scabiei*. Geoffroy has called them *cirons de la gale*, and De Geer, *mittes de la galle*. They have been drawn in the Dictionnaire des Sciences Medicales, and are represented as having six legs, and two small horns, magnified 250 times, so that they appear as large as ordinary beetles. Alibert has carefully *examined many scabious patients, and declares* he could never find any sarcoptes or acari; and Biett, who is a very careful and reflecting man, has examined a large number of patients with the person employed by Gales to draw the insects, but they could never discover any in the vesicles under any circumstances. The painter afterwards owned to Biett that he had never seen any one of the insects in the itch vesicles or pustules, but always outside them. Lugot continued these investigations in 1819, 1820, and 1821, with the strongest lens, but with the same result as the preceding. This is strong authority against the *vital itch*, and goes a great way to upset the force of the observations of Gales and the others.

CHICAGO.

THE STOCKYARDS AND PACKING TOWN; INSANITARY CONDITION OF THE WORLD'S LARGEST MEAT MARKET.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

IT was in mid-November that I left St. Louis for Chicago. The train first followed the banks of the Mississippi and went under the great St. Louis bridge. The immense *accumulation of railway wagons and the multiplicity of* railway lines were remarkable. Very ugly red brick warehouses often blotted out the sight of the majestic Mississippi, while numerous yellow refrigerator railway vans suggested the tasteless meat and unappetising *menu* of the American cold storage dinners. During the whole day, in spite of the advanced season, beautiful summer weather prevailed. The country was flat and uninteresting. The leaves still hung to the trees, though in a dried up condition. In the dining car roses decorated the tables and after so much sunshine and such summer experiences the contrast on arriving was the more painful to note. At Chicago the sky was black, though there was no fog or mist, and huge clouds of dense smoke spread over the city like a pall. The streets were dark and gloomy and being hedged in on either side by ugly houses ranging from ten to 20 storeys in height it seemed, on leaving the station, like penetrating some sinister ravine rather than walking along the best streets of a great and wealthy city. But for the gas burning in the shop windows and various electric advertising contrivances it would have been quite difficult to see. At rare intervals a little pink speck indicated that some abortive effort had been made at electric lighting and that was all the trace noticeable of municipal enterprise. Miserably slow horse tramcars rumbled along badly paved dark streets where desperate men not infrequently *stop and rob pedestrians.* Murders have increased fourfold in America within recent years and such being the case the streets should be well lighted. This, my first impression, did not lead me to anticipate that any very progressive information or example would be available at Chicago. Yet I had soon to recognise that a very bold and gigantic scheme was in process of execution to divert the drainage which used to fall into Lake Michigan and to direct it inland, where it will not injure the inhabitants of Chicago, whatever harm it may do to those who live elsewhere. By this means an inland river course is contaminated but the Chicago water-supply, which is derived from the lake, will no longer be exposed to the risk of receiving some of the city sewage. Then, again, it must be admitted that according to the official figures the death-rate is not high if Chicago is compared with other large industrial centres. The sanitary authorities have also much to show that indicates careful organisation to secure prompt action in dealing with cases of infectious disease, so that early isolation and thorough disinfection may protect the community at large from the danger of epidemics.

In spite of all this it is at once evident that those inhabitants of Chicago who take an earnest interest in the social conditions of their great city in any case are not satisfied. One great stain is ever present; it is always in sight and sometimes it is not only seen but it is smelt and felt. The greatest of the local industries, that for which Chicago is celebrated all over the world, is the principal cause of complaint. It is from the stockyards and "packing town" that the ever visible black smoke emanates which conceals the sky and the sun from that part of Chicago over which it is spread. Wherever the wind blows the smoke, there it deposits soot, blackens the houses, the clothes, and the hands and the faces of the people. With it come unpleasant odours of a meaty nature and as of burnt animal matter which seems to parch the throat and this helps to explain the difficulty that many inhabitants of Chicago experience in articulating their words distinctly. But the smoke nuisance, serious as it is, only constitutes the outward and visible sign—visible from an immense distance—of the abominations perpetrated within. The providing of food, of every form of animal food, should be a matter of public concern. It is a sacred trust, for so much depends on the sanitary condition of slaughter-houses and the efficient inspection of meat. In Great Britain and all over Europe the feeling gains ground that private slaughter-houses should be abolished and model public abattoirs instituted in their stead either by the State or by the municipalities. In previous studies of this subject descriptions have been given showing how at Berlin the State and the municipality combined to establish a model cattle market and abattoir.[1] An account likewise appeared relating how so far back as the year 1836 the municipality of Brussels built a public abattoir and abolished all private slaughter-houses.[2] It was just about this same period that from being merely a fort and a settlement Chicago reached the more dignified position of incorporation as a city and in 1837 it had a population of 4170 inhabitants. What an immensely wealthy town Chicago would have been to-day had it then and there followed the example of Brussels and built its own abattoir. But it need not have adopted such a progressive policy so early in its history. In 1850 there were but 29,963 inhabitants, though by 1860 this number had grown to 109,206. There was then still time to act and it was not till 1870 that Chicago became one of the leading commercial centres of the United States. There were then 306,605 inhabitants. The next year a large portion of the city occupying three and a half square miles, and on which stood 17,500 buildings, was burnt down. The property destroyed was estimated at £40,000,000 and some 100,000 people were rendered homeless. Here, then, was an opportunity for the adoption of heroic measures, and in view of likely future local developments the most obvious of all such measures was the prohibition of private slaughtering so as to secure at once the protection of public health and the creation of public revenues. In 1903 the population of Chicago was estimated at 1,873,880 and the killing to provide meat for such a number of people represents a large and remunerative business. But this is a very small part of the killing done at Chicago. The supply of animal food by cold storage, by curing, pickling, or tinning is provided at this centre for all parts of America—indeed, for all parts of the world.

---

[1] Excerpts only have been transcribed.

It is estimated that between 3,000,000 and 4,000,000 cattle are taken to the Chicago stockyards annually. The number of hogs is set down at from 7,000,000 to 8,000,000 and there are from 3,000,000 to 4,000,000 sheep. Some of these animals are sold to farmers, to cattle breeders, or to exporters of live cattle destined to be slaughtered abroad. But the greater proportion, from two-thirds to three-quarters of these animals, is killed on the spot. Berlin may serve as a comparison with Chicago, for there we find probably the largest State and municipal abattoir in existence. All that relates to the transport of the cattle and so on is in the hands of the State, while the buildings for slaughtering belong to the Berlin municipality. The system of payment is, as usual, a fixed charge per head for the use of the accommodation and the control supplied by the authorities. The highest charge in proportion to their size and value is that made for hogs. This is natural because much more careful examination is necessary. The owner therefore has to pay 1.50 marks for every pig killed. But of this sum no less than .80 pfennigs go to the cost of examination, 25 pfennigs for the working expenses, and 55 pfennigs as the salary of the microscopist; so that the charge for the actual slaughtering is only 70 pfennigs. A higher price might be obtained in America than in Germany, yet even at the Berlin estimate we may reckon in American money 40 cents per hog and at the rate of 6,000,000 hogs this would make an income of $2,400,000 per annum, but there were actually 6,648,449 hogs killed here in 1902. For cattle at Berlin the charge is 1.90 marks per head, of which only 50 pfennigs are required for examination. In America this would equal in round figures half a dollar, or for 3,000,000 cattle, including calves, $1,500,000 per annum. There remain some 3,000,000 sheep at 30 cents each, or $900,000. Therefore the cattle, hogs, and sheep, even at the Berlin rate for slaughter-house fees, would at Chicago bring in at least $4,800,000 per annum. But a great amount of poultry is killed here and there is also a very large horse market, so that the present amount of business done might easily bring in more than $5,000,000 or £1,000,000 per annum to the Chicago municipality. With such an income it would be easy to defray the working expenses and to repay the loan made for building the public abattoirs; there would then remain an increasing revenue which the town might utilise for the reduction of taxation or for the carrying out of works of public utility. Such is the opportunity which the municipality of Chicago has missed.

Nor does the matter end here. It must be clearly understood that no one possessing technical knowledge of the question would buy meat from Chicago if it were possible to obtain it at about the same price and quality from an efficiently controlled municipal slaughter-house such as exists at Brussels, Berlin, Paris, and many other great railway and canal navigation centres. It will scarcely be believed, but it is nevertheless a fact, that at Chicago not only is there no municipal abattoir but there are no private abattoirs in the technical sense of the term. It is true that millions of animals are slaughtered annually but they are not slaughtered in slaughter-houses. For many hours I wandered about the stockyards and I saw many animals killed but nowhere could I discover the smallest trace of a slaughter-house. The animals were killed not in abattoirs but in mills or factories—huge, hideous box-shaped buildings five and six storeys high. The pigs notably were killed on the second or third floor of these buildings. As for all the principles of sanitation laid down to govern the construction of abattoirs, these were ignored from the first to the last. Consequently the insecurity is so great that several nations of the more civilised parts of the world have thought it necessary to enact special laws against Chicago. The exportation of pork products from Chicago to Germany, Austria, France, and Denmark is prohibited unless accompanied by a certificate issued, not by any local authority, but by the Government of the United States itself. The entire American nation thus pledges its honour that no product that has not been carefully examined under the microscope shall be exported from Chicago to those countries. As for American citizens or for British citizens it does not matter. They may swallow trichinæ wholesale; no one seems to think it is worth while to attempt to protect them. Yet it was formerly shown that of the hogs taken to market 3 per cent. were infected with trichinæ. Fortunately some Governments, especially the German Government, have taken energetic measures to prevent the spread of trichinosis and therefore hog rearers and dealers are more careful. Greater attention is now bestowed on the rearing of pigs and consequently the prevalence of this serious disease is considerably reduced. The inspectors appointed by the central Government at Washington cut three different samples from each pig killed at Chicago which is to be exported to the countries mentioned. These samples are examined for trichinæ under the microscope. Instead of 3 per cent., as formerly, only 1½ per cent. of the animals examined at Chicago are found to be infected with this disease. But the pork products prepared for the American and the British markets are not so examined and this though it is known that on an average 1½ per cent. of the total are infected with trichinæ. Fortunately, this parasite is generally destroyed by cooking but there are some sausages made with raw pig's meat and it is difficult to understand why precautions judged necessary by so many continental nations should not be equally needed to protect the American public and the British public. Of course, if there were at Chicago an abattoir managed on similar lines to that at Berlin none of the existing hostile legislative and protective measures now enforced against the produce of the Chicago stockyards would be necessary nor would they have been enacted.

---

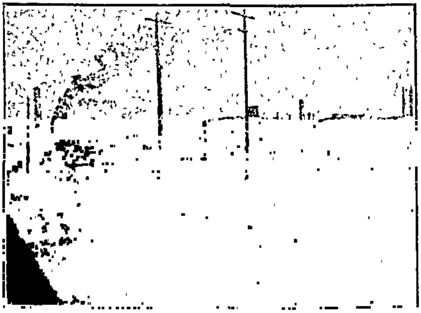
[1] THE LANCET, July 14th, 1894, p. 101.

[2] THE LANCET, Dec. 17th, 1892, p 1409.

Several years ago when in Servia, I was consulted by the authorities as to what could be done to improve the material resources of the country. The founders of both rival dynasties, the Karageorgewitch and the Obrenovitch houses, had been engaged in the rearing of pigs. Indeed, pigs and prunes are the principal products of the country, so I urged that instead of sending at great cost living pigs to the Hungarian markets a model slaughter-house should be constructed according to the latest principles of sanitary science. Close to Belgrade, either on the banks of the Save or of the Danube, there is an abundance of vacant space admirably suited for such a purpose. Here shambles made mainly with iron and glass, bathed in daylight and sunlight, with double ventilating roofs, could be constructed. Of course, there would be good laboratories for bacteriological research and microscopical examination. With such measures and precautions the products might attract many purchasers by reason of the security which enlightened scientific and State control would insure. Is it now too late for such arguments to be applied at Chicago?

As the stockyards of Chicago cover an area of some 500 acres no general view can be obtained but the accompanying illustration (reproduced from a photograph which I was able to take of a small portion of the stockyards) shows three things. First, that there is a large amount of vacant ground in their immediate neighbourhood; therefore a model abattoir could be built sufficiently close for the continued utilisation of such portion of the existing plant as is fit to be preserved. Secondly, the factory character of the buildings will be noted, though it will be difficult for anyone to believe who has not seen that it is in such buildings that the animals are actually slaughtered. Thirdly, one chimney, at least, forcibly illustrates with what recklessness and utter indifference to public welfare the atmosphere is befouled by the blackest of smoke.

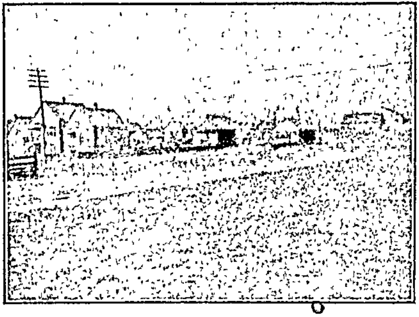
FIG. 1.



Chicago. The stockyards. View showing the factory character of the buildings in which the slaughtering is done, the amount of vacant space at hand, and the smoke nuisance.

The next illustration is reproduced from a photograph which was taken from an open and large space of waste ground in Forty-eighth Street. Here a portion of "Packing Town" may be seen—namely, the wooden cottage homes of the people who work in the stockyards at packing and preparing the meat to be sent to all parts of the world. In the background the smoke and escaping steam from the stockyards can again be noted. It will be seen how sparsely the ground is built upon and that, therefore, land must be comparatively cheap. Consequently there should be no insurmountable financial difficulty in securing a suitable and sufficiently extensive site for the erection of sanitary slaughter-houses such as exist in most civilised countries. In the construction of the cottages it will be observed that in spite of the abundance of land they are sometimes placed too close to each other. The cottages to the left of the picture have barely three feet of open space between them. This would not matter so much were it not for the fact that some of the cottages are so long or deep that windows have to be cut in the walls of the narrow passage between the dwellings. Such windows receive insufficient air, but little light, and no sunshine. This is one of the many instances showing with what thoughtless disregard of human health interests cheap dwellings are sometimes erected. On the other hand, the vast amount of waste ground, the scattering of the dwellings, and the absence of overcrowded streets are some of the principal reasons why the insanitary condition of the stockyards has not produced as much injury to the people who work in them as otherwise might be expected.

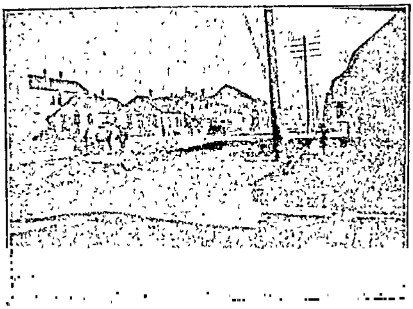
FIG. 2.



Chicago. "Packing Town," from Forty-eighth Street, showing the workers' cottages, the large amount of open space, and the stockyards smoke nuisance in the rear.

Going to the more populated end of Forty-eighth Street—that is, near Ashland Avenue which is the main thoroughfare of the district—I was startled to find that men and horses were engaged in ploughing the street. It is true that they were not going to sow wheat in the middle of the thoroughfare but the fact that it was possible to plough a street without interfering too much with the traffic indicated how slight that traffic must be and consequently how very little crowding there is in the neighbourhood. As it will certainly be maintained that the vital statistics do not demonstrate that any great harm is done by the stockyards, it is important to bear these facts in mind. It does seem as if the unwholesomeness of the stockyards is to a large extent counteracted by the healthy character of the workpeople's houses. In Berlin, Paris, and many other European towns there are reverse conditions—namely, proper, clean slaughter-houses with plenty of light and sunshine but the workers are compelled to live in crowded tenement houses built in the narrow streets of teeming cities. The accompanying illustration (Fig. 3) shows the enormous amount

FIG. 3.

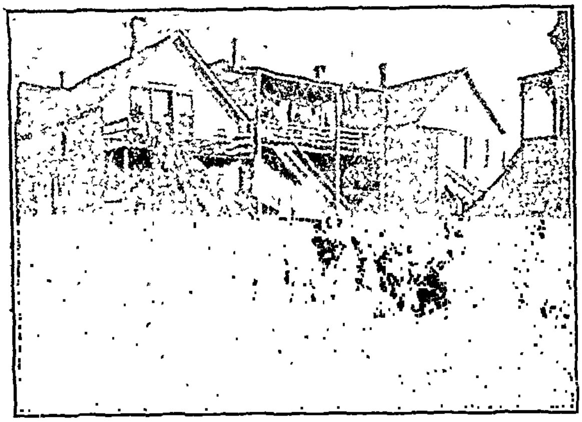


Chicago. Ploughing in Forty-eighth Street.

of open space enjoyed even in the more populated end of Forty-eighth Street. The photograph was taken at the lunch hour. In the foreground the horses are resting by the side of the plough and it will be seen how they have ploughed up the earth in the middle of the street. To the right a curbstone stands up above ground to the height of more than one foot, a very convenient contrivance for tripping people up in the dark. The object of ploughing the middle part of the street was to loosen the earth so that it might more easily be lifted and thrown on the other side of this curbstone and thus the level of the side walk would be raised a little above that of the street. Of course, there is no pavement and, indeed, the whole of the district is more like a country settlement than a town. When the population increases, if great reforms are not accomplished at the same time, there will be serious consequences.

Finally, I took a photograph of a house in this same neighbourhood where there has been an exceptional prevalence of tuberculosis (see Fig. 4). The front opens on to a very broad street so I photographed the back of the house where the conditions are not so good and yet it will be seen how large is the amount of open space. Indeed, no fault can be found topographically with this house. The workpeople engaged at the stockyards may consider themselves very fortunate to be able to live in what, so far as breathing space is concerned, is more like the country than a city boasting of nearly 2,000,000 inhabitants, but when they leave their homes to work within the stockyards then indeed they have good cause to complain.

Fig. 4.



Chicago. "Packing Town." Workers' dwelling where there have been many cases of tuberculosis.

(*To be continued.*)

THE SERVICES.

Royal Navy Medical Service.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon John Speare Lambert has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated Dec. 22nd, 1904) and Surgeon Arthur Heaword Prichard has been placed on the Retired List (dated Dec. 19th, 1904).

The following appointments are notified:—Surgeons: E. R. Grazebrook to the *Cambridge*, additional, for the *Theseus*, and F. J. McKenna to the *Hussar* on commissioning.

Royal Army Medical Corps.

Lieutenant-Colonel (temporary Surgeon-General) A. Keogh, C.B., to be Colonel, vice W. Donovan, C.B., promoted (dated Dec. 2nd, 1904). Lieutenant-Colonel J. I. Routh to be Colonel, vice A. Keogh promoted (dated Dec. 3rd, 1904). Colonel A. H. Anthonisz is placed on retired pay (dated Dec. 22nd, 1904).

Army Medical Staff.

Colonel W. Donovan, C.B., from Royal Army Medical Corps, to be Surgeon-General, vice Sir W. Taylor, K.C.B., K.H.P. (dated Dec. 2nd, 1904). Colonel (temporary Surgeon-General) A. Keogh, C.B., from Royal Army Medical Corps, to be Surgeon-General, to complete establishment (dated Dec. 3rd, 1904).

Army Medical Service.

Surgeon-General A. Keogh, C.B., is appointed Director-General, vice Sir W. Taylor, K.C.B., K.H.P., retired (dated Jan. 1st, 1905).

Army Medical Reserve of Officers.

Captain H. W. Thomson, Glasgow Companies, Royal Army Medical Corps (Volunteers), to be Surgeon-Captain (dated Dec. 24th, 1904).

Volunteer Corps.

Royal Garrison Artillery (Volunteers): 1st Gloucestershire: Surgeon-Lieutenant-Colonel D. S. Davies resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated Jan. 4th, 1905). 2nd Sussex: Surgeon-Major H. Habgood to be Surgeon-Lieutenant-Colonel (dated Jan. 4th, 1905).

Rifle: The Cambridge University: Surgeon-Lieutenant H. B. Roderick to be Surgeon-Captain (dated Jan. 4th, 1905). 1st Bucks: Supernumerary Surgeon-Major (Brigade-Surgeon-Lieutenant-Colonel) W. H. Bull (Senior Medical Officer, Home Counties Volunteer Infantry Brigade) to be Surgeon-Lieutenant-Colonel and to remain seconded (dated Jan. 4th, 1905). 1st Sutherland (The Sutherland Highland): Surgeon-Lieutenant S. Elliot resigns his commission (dated Jan. 4th, 1905). 7th Middlesex (London Scottish): Surgeon-Lieutenant-Colonel J. Cantlie resigns his commission and is granted the honorary rank of Surgeon-Colonel with permission to wear the prescribed uniform (dated Jan. 4th, 1905).

Royal Army Medical Corps (Volunteers).

The London Companies: Captain A. Granville is seconded whilst holding a civil appointment under the Egyptian Government (dated Nov. 28th, 1904); Surgeon-Captain E. A. Snape, from the 2nd Middlesex Royal Garrison Artillery (Volunteers) to be Captain (dated Jan. 4th, 1905). The Manchester Companies: Gordon William Fitzgerald to be Lieutenant (dated Jan. 4th, 1905).

Indian Honours.

Major Robert Bird, I.M.S., surgeon to the Viceroy and Governor-General of India, has been appointed a Companion of the Most Eminent Order of the Indian Empire.

Mountainous Tibet.

We have already dwelt upon the very difficult geographical features of the country which was the scene of the late Lhasa expedition. The following will give some idea of these and of the altitudes traversed by the troops. The Karo-la has an elevation of 18,500 feet; the mean altitude is over 16,500 feet, the valleys being from 14,500 to over 17,000 feet, the peaks from 20,000 to over 24,000 feet, and the passes from about 16,500 to 19,000 feet.

The War in the Far East.

The first act at any rate in the tragic drama that has been so long going on in the Far East has come to an end and the curtain has fallen with the capitulation of Port Arthur. Whether it is to be continued or not will, we suppose, materially depend upon the internal state of affairs in Russia. The news of the surrender of the beleaguered fortress has been received by all civilised nations with an intense feeling of relief. General Stoessel, whose heroic defence all must admire and respect, has had the moral courage to accept the inevitable and to realise that further resistance would only lead to increased suffering and a perfectly futile sacrifice of life on the part of his devoted garrison. This much may be said for the Japanese, they regarded that the seizure of the fortress by the Russians in 1897 and its continued occupation by them since that time meant a matter of life and death to their nation. They have now retaken possession of Port Arthur at an enormous sacrifice of life and treasure and with an exhibition of desperate courage and pertinacity of purpose on their part which have probably never been exceeded in the history of war. We have no intention to compare the defensive difficulties of Ladysmith and Mafeking in the late Boer campaign with those of Port Arthur but we may gratefully recall the fact that the defence of the former, happily for the British, proved successful. It is stated that there were 15,000 wounded men in the already overcrowded hospitals with only 5000 convalescents and able-bodied men available for fighting in Port

Arthur at the time of its surrender. The absorbing news regarding the capitulation of Port Arthur has naturally engrossed everybody's attention to the exclusion of events occurring elsewhere. There is, however, little or no news concerning the belligerent armies. They still remain inactive but confronting one another on the Shaho. The Russian field kitchens used by the troops are very good and have enabled them to partake of a warm meal at all sorts of times and places. The ambulatory kitchens supply them with hot soup and tea at night or during an engagement. The reports regarding the health of the troops are somewhat contradictory and it is very difficult to ascertain their actual condition in this respect.

A message from Moscow to the *Novoe Vremya* says that as 12 per cent. of the wounded from the Far East return with open bullet wounds the city council has decided to acquire a Roentgen-ray laboratory for the purpose of searching the wounds of those brought into Moscow.

A telegram has been received in Moscow from the city Red Cross representative in the Far East that out of the 120 packets sent there in July and August over 100 were lost, including a quantity of Roentgen-ray apparatus so necessary for use in treating the wounded.

Major Louis L. Seaman, who is a major and surgeon in the United States Volunteers, has just published a book on the Japanese Army in Manchuria. Major Seaman served in Cuba during the Spanish-American war, in the Philippines, and with the allies in China at the time of the Boxer rising, and is consequently entitled from his experience to speak with authority. Major Seaman is unstinting in his praise of the Japanese Army Medical Service, both from the sanitarian standpoint and from that of practical and scientific medicine and surgery. The object of the Japanese Medical Service has been to prevent rather than to cure disease, and how successful the effort has been is shown in the fact that fighting in a notoriously unhealthy country the Japanese army has suffered but little from [illegible] of which 6636 were cases of the wounded; of the entire number up to that time only 34 had died." The results at the naval hospital at Sasebo were equally gratifying. Major Seaman gives a long account of the medical officer in the field and institutes comparisons between the Japanese army medical department and those of the most highly civilised nations, which are by no means flattering to the latter It would appear from a perusal of Major Seaman's book that the Japanese Army Medical Service has not only successfully imitated the best European methods but has even improved upon them.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7617 births and 6567 deaths were registered during the week ending Dec. 31st, 1904. The annual rate of mortality in these towns, which had been 18·6, 19·2, and 19·4 per 1000 in the three preceding weeks, further rose to 22·4 per 1000 last week. In London the death-rate was 21·0 per 1000, while it averaged 23·1 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 9·6 in York, 11·7 in King's Norton, 11·8 in Willesden, 12·0 in East Ham, 12·2 in Walthamstow, 12·8 in Leicester, and 13·1 in Handsworth (Staffs.); the highest rates were 28·6 in Huddersfield, 29·5 in Preston, 30·0 in Sunderland, 32·4 in Middlesbrough, 33·0 in Stockton-on-Tees, 33·3 in Oldham, 35 2 in Manchester, and 36·7 in Hanley. The 6567 deaths in these towns last week included 475 which were referred to the principal infectious diseases, against 438, 421, and 399 in the three preceding weeks; of these 475 deaths, 152 resulted from measles, 105 from whooping-cough, 80 from diphtheria, 54 from diarrhœa, 50 from scarlet fever, 31 from "fever" (principally enteric), and three from small-pox. No death from any of these diseases [illegible] on, Willesden, Hornsey, [illegible] ng, Handsworth (Staffs.), [illegible] or Rotherham; while the [illegible] in Great Yarmouth, Bristol, Hanley, Burton-on-Trent, Grimsby, Nottingham, Liverpool, St. Helens, Oldham, Blackburn, Stockton-on-Tees, and South Shields. The greatest proportional mortality from measles occurred in Devonport, Bristol, Leicester, Grimsby, Nottingham, Liverpool, St. Helens, Stockton-on-Tees, Gateshead, Tynemouth, and Merthyr Tydfil; from scarlet fever in Northampton, Coventry, and Blackburn; from diphtheria in East Ham; and from whooping-cough in Great Yarmouth, Bristol, Hanley, Derby, St. Helens, Oldham, Middlesbrough, and South Shields. The mortality from "fever" and from diarrhœa showed no marked excess in any of the large towns. Of the three fatal cases of small-pox registered in these towns last week one belonged to Bolton, one to Preston, and one to Bradford. The number of small-pox cases under treatment in the Metropolitan Asylums hospitals, which had been four, six, and 14 at the end of the three preceding weeks, had further risen to 17 at the end of last week; five new cases were admitted during the week, against one, two, and nine in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2386, against 2490, 2403, and 2393 at the end of the three preceding weeks; 201 new cases were admitted during the week, against 263, 242, and 242 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 448, 487, and 416 in the three preceding weeks, rose again last week to 521, and were 115 above the number in the corresponding period of last year. The causes of 123, or 1·9 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Leicester, Nottingham, Bolton, Bradford, Leeds, and in 29 other smaller towns; the largest proportions of uncertified deaths were registered in Burton-on-Trent, Birmingham, King's Norton, Liverpool, Bootle, Warrington, Manchester, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19·7, 22·6, and 21·2 per 1000 in the three preceding weeks, rose again to 21·6 per 1000 during the week ending Dec. 31st, but was 0·8 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15·3 in Dundee and 16·2 in Leith, to 25·4 in Aberdeen and 27·7 in Perth. The 715 deaths in these towns last week included 40 which were referred to whooping-cough, 20 to measles, 12 to diarrhœa, two to scarlet fever, two to diphtheria, and two to "fever." In all, 78 deaths resulted from these principal infectious diseases last week, against 68, 80, and 90 in the three preceding weeks. These 78 deaths were equal to an annual rate of 2·4 per 1000, which was 0·8 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 38, 32, and 31 in the three preceding weeks, rose again last week to 40, of which 29 occurred in Glasgow, four in Edinburgh, three in Perth, and two in Leith. The deaths from measles, which had been ten, 17, and 19 in the three preceding weeks, further increased to 20 last week, and included 15 in Aberdeen and four in Glasgow. The fatal cases of diarrhœa, which had been 15, 16, and 25 in the three preceding weeks, declined again last week to 12, of which six were registered in Glasgow, three in Aberdeen, and two in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 204, 206, and 174 in the three preceding weeks, rose again last week to 184, and were seven in excess of the number in the corresponding period of the preceding year. The causes of 29, or more than 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·2, 25 3, and 24·5 per 1000 in the three preceding weeks, rose again to 25 0 per 1000 during the week ending Dec. 31st. During the 13 weeks ending on that date the death-rate has averaged 23·1 per 1000, the rates during the same period being 17·0 in London and 16·2 in Edinburgh. The 182 deaths of persons belonging to Dublin registered during the week under notice were four in excess of the number in the preceding week, and included 26 which were referred to the principal infectious diseases, against 14, 10, and 12 in the three preceding weeks; of these, 16 resulted from measles, six from diarrhœa, two from whooping-cough, one from scarlet fever, and one from "fever," but not any from small-pox or diphtheria. These 26 deaths were equal to an annual rate of 3·6 per 1000, the death-rates last week from the principal infectious diseases being 1·4 in London and 1·3 in Edinburgh. The fatal cases of measles, which had been six and ten in the two preceding weeks, increased last week to 16. The deaths from diarrhœa, which had been one, three, and one in the three preceding weeks, rose again to six last week. The 182 deaths in Dublin last week included 40 of children under one year of age and 48 of persons aged 60 years and upwards; the deaths of infants slightly exceeded the number in the preceding week, while those of elderly persons showed a decline. Three inquest cases and three deaths from violence were registered; and 74, or more than a two-fifths, of the deaths occurred in public institutions. The causes of eight, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

Correspondence.

"Audi alteram partem."

HOW THE GENERAL MEDICAL COUNCIL SUPPORTS ITS VISITOR AND INSPECTOR.

To the Editors of THE LANCET.

SIRS,—Having completed my work as inspector of the General Medical Council, and after the fierce attack made on Nov. 28th by its (past) President upon the accuracy of the report of the visitor and inspector of the Council upon the final examination of the University of Edinburgh, and my inability to get Sir William Turner to give both sides of the question which has been raised, I must ask you to publish the following inclosures.

I am, Sirs, yours faithfully,
Grosvenor-street, W., Dec. 26th, 1904. THOMAS BRYANT.

27, Grosvenor-street, London, W., Dec. 6th, 1904.

DEAR SIR WILLIAM,—I have just read and re-read the speech you made from the chair at the stormy meeting of the General Medical Council of Nov. 28th on the proposal of the chairman of the Examination Committee for the adoption of the report of the committee on the final examination of the University of Edinburgh, and I must add that I read your speech with sorrow and astonishment, for it was quite clear that you had on the occasion allowed your anger to obscure your judgment and consequently to make statements such as the facts in the report I signed with Sir G. H. Philipson by no means justify.

For instance, you quoted the following passage from the inspector's report,[1] and then said "you were going to *question the truth of the paragraph*," and you did this without drawing any attention of the members of the Council to the reasons given in the visitor and inspector's report for writing that paragraph, and which are to be read in the two paragraphs preceding the one you had quoted on page 13.[2]

Might I ask, are not the above reasons for such an opinion as is contained in the paragraph you quoted worthy of consideration? and was it quite fair (to use a mild expression) for the President of the Council to put only one side of a question before its members on such an important matter as was then under consideration?

You then made some rather wild remarks about a clinical examination at the bedside, as you understand it, in Edinburgh and drew some inferences which are your own, whilst my remarks, which you quoted (p. 14) and made fun over, had special reference to a more humane and better method such as is followed by the professor of surgery of Edinburgh University and successfully practised by him and others, the adoption of which would enable your professor of clinical surgery to give up using sick patients in a hospital ward for purposes of examination in surgical anatomy and surgical operations in the presence of other sick patients, as well as of their male and female visitors, and more particularly when these same surgical patients had been previously for the better part of two hours in the hands of the candidates for examination in taking a report of their cases.

Am I to understand that you approve of the practice my colleague and I saw carried out in the way described and which we say is neither humane nor decent? for the faculty of your University, I was pleased to read, admits that the criticism of the visitor and inspector with respect to patients' friends in the wards is reasonable, page 33, (2) and that other of our suggestions will have the careful consideration of the faculty. At the same time the faculty, in page 35 of the report, condemn the visitor and inspector for the opinion they gave and which is contained in the sentence you have quoted. When that sentence was penned, as I have shown to have been the result of the extraordinary arrangements which have been described and which must have spoiled any clinical surgical examination, however otherwise excellent.

The questions the examiners gave may have been good, but in the practical examination they were not applied and were not tested; the examination, in fact, was all talk, nothing practical.

I could say something about the report of the Examination Committee, for it illustrates the "doubtful" condition of the chairman's mind. He saw only in the report what he wanted to see and nothing else. The report, moreover, of the Examination Committee is not accurate.[3]

I write this letter to ask what you mean to do. You admit that "to three-fourths of the examination the visitor and inspector could not have spoken in much higher terms," and this pleasant part of the report you accept as true, whereas you deny the truth of the criticisms of the surgical fourth which are as true as the other three-fourths.

If you have any thought of making the matter clear, so much the better. At present both you and the Examination Committee, by singular methods, obscure the truth which must be made clear.—Believe me, yours faithfully,

Sir W. Turner, K.C.B. THOMAS BRYANT.

Receiving only an evasive answer to this letter I sent the following:—

Grosvenor street, W., Dec. 20th, 1904.

DEAR SIR WILLIAM,—I have just returned from Oxford, having finished the inspection of the final examination in medicine of the University and find your answer to my letter of Dec. 6th.

In your letter you have evaded the questions I put to you

---

[1] "During the three afternoons we (the inspector and visitor) devoted our attention to this part of the surgical clinical examination, not a patient was placed in the position of one who had to undergo the operation suggested. No mention was made of assistants or the use of instruments which might be required. No attempt was made practically to get out of any candidate any precise knowledge of the relation of an artery or nerve beyond what book knowledge would have given him; indeed, the examination was so unsatisfactory that we were enabled to realise the truth of the adverse criticisms we have heard of this method of examination in a way which we never before believed to have been possible."

[2] "Immediately on the conclusion of Part A of this clinical examination the candidate was required to carry out Part B and under another examiner to indicate upon the patient whose case he had reported, and upon whose case he had been examined, the lines of incision for two operations which had been previously indicated; upon the same patient he had, moreover, to be examined on surgical anatomy and surgical procedures, and it must be added that all this serious work was carried out in a ward to *which the patients' friends and visitors, male and female, were freely admitted.* It need hardly be added that, under these circumstances, exposure of any part of the patient's body which was so essential for examination purposes was inadequate or impossible and that the examination suffered seriously in consequence."

[3] Page 42. The chairman of the Examination Committee finds fault with the visitor and inspector for not having expressed an opinion as to the standard of the examination in [illegible]
when the slightest care woul [illegible]
of only two candidates had b [illegible]
wished that such a blunder had been committed to give him some reasonable excuse for fault finding. In the same page he states that no opinion is expressed by the visitor and inspector as to the standard of the oral examination in general surgery (p. 18). Had the chairman read to the bottom of page 19 he would have read that they were (visitor and inspector) much pleased with both the oral and practical surgical examination.

Page 44, the last 17 lines. After a quotation, the Examination Committee state that the medical faculty of the University do not admit the accuracy of the statements of the visitor and inspector and *from notes furnished by the examiners* the faculty is satisfied that the examination in surgical anatomy was not only appropriate but very searching. Happy faculty! who are satisfied with conditions they did not see and with an examination they did not hear, when the visitor and inspector *saw* what they have described on *three consecutive afternoons* and heard the examinations upon which they have given their opinion and to which they adhere and I therefore for a second time repeat them in a categorical form and trust that you will consider them worthy of your attention.

Question 1.—Was it quite fair (to use a mild expression) for the President of the General Medical Council to put only one side of a question before its members?

Answer ....

Question 2.—Do you deny the truth of the following paragraph? Page 13 of report.

Immediately on the conclusion of Part A (about which no remarks are called for) "the candidate was required to carry out Part B, and under another examiner to indicate upon the *patient whose case he had reported*, and upon whose case he had been examined, the lines of incision for two operations which had been previously indicated; upon the same patient he (the candidate) had, moreover, to be examined on surgical anatomy and surgical procedures, and it must be added that all this serious work was carried out in a ward *to which the patients' friends and visitors, male and female, were freely admitted.*

Answer ....

Question 3.—Do you consider that such arrangements are from any point of view satisfactory?

Answer ....

Question 4.—Do you think it possible under such arrangements as have been described that any examination on surgical anatomy and surgical procedures could be otherwise than a failure?

Answer ....

Believe me, Sir William, yours faithfully,

Sir W. Turner, K.C.B. T. BRYANT.

To which on Dec. 23rd I received the inclosed:—

University of Edinburgh, Dec. 23rd, 1904.

DEAR MR. BRYANT,—I am in receipt of your letter of Dec. 20th, in which you ask me to reply to a series of questions put by you in a categorical form. In reply, I would state that the report on the final examination of this University is a public document open to criticism. It has been criticised by the Examination Committee of the Medical Council, by the Faculty of Medicine of this University, and by myself as the representative of the University on the Council. Those interested in the matter have the means therefore of forming an opinion on the points under discussion.

With all respect to yourself personally I decline to be further catechised on the subject.

I remain, very truly yours,

Thos. Bryant, Esq. WM. TURNER.

HÆMOCONIA.

To the Editors of THE LANCET.

SIRS,—I read with much interest Dr. Andrew Love's article on Hæmoconia in THE LANCET of Dec. 24th, 1904, p. 1781. I have been investigating those bodies for a considerable time and my observations regarding their classification correspond with his. I have found them in every blood I have examined with the exception of two cases. The blood in these cases was abnormal in this respect that coagulation of the drop appeared to take place as soon as the puncture was made. I had a difficulty in spreading the films and they showed on examination large solid-looking plates of fibrinous material. Hæmoconia were entirely absent in both cases, although I searched for them for hours. The group No. 2 of Dr. Love's classification I have found freely motile in a film closed with vaseline after three days. I have found group No. 2 in a urine I examined and in this patient's blood these bodies were present in great abundance; the whole plasma appeared scintillating with them. As yet I have come to no conclusion as to their prognostic significance. I have found them as freely in persons who are in perfect health as in those who suffer from disease. In some, however, there are few to be found, while in others they are numerous. I examined my own blood and found them very numerous and so far as I know was suffering from no disease at the time. I have also failed to stain them though I have tried every method available. At present I should not care to advance any theories regarding their function but I think they are well worthy of further investigation.

I am, Sirs, yours faithfully,

Edinburgh, Dec. 27th, 1904. FREDERICK PORTER, M.B. Edin.

INSTRUCTION OF THE LAITY IN THE EARLY SIGNS OF CANCER.

To the Editors of THE LANCET.

SIRS,—Mr. Skene Keith in his letter to THE LANCET of Dec. 24th, 1904, p. 1811, in one sentence objects to the public being instructed in the early signs of cancer on the ground that an omniscient first-aid graduate might undertake to differentiate between a malignant and an innocent growth, and in the next sentence says, "What the public require to be taught is to seek advice early." How the laity is to be "taught to seek advice early" without being educated in the early signs of cancer Mr. Keith has failed to explain and has at the same time entirely overlooked the fact that my letter from beginning to end advocates early appeal, not to the first-aid graduate but to the medical man as the judge who is to decide whether a growth is sufficiently suspicious to need removal. Quacks who flourish on cases of cancer, real or imaginary, will always exist; the number of their victims can only be diminished by educating the public in the signs and treatment by operation of cancer in its early stages.

The suggestion that many medical men need instruction in the early signs of cancer, true as I know it to be, is beside the mark, for the simple reason that however well informed the medical man may be he cannot recognise a case of cancer in its early stage unless the patient comes to be examined, and the patient who usually regards pain as the distinctive feature of cancer does not consult a medical man until driven to do so by the onset of pain, which frequently means that the growth has involved surrounding structures and is totally beyond cure or is curable only by a very severe and mutilating operation.

Mr. Keith wishes to know whether prevention includes the removal of every growth as soon as found. To this the answer is, Certainly not. A growth which has no suspicion of malignancy, is not enlarging, is not ulcerated, and is producing no symptoms should, unless its removal is desirable for æsthetic reasons, be left severely alone. But any growth which has any suspicious sign of malignancy, such as increase in size, persistent ulceration, or pain, should be removed. Removal of these small defined growths is easy, the risk of operation infinitesimal, and the chances of recurrence small. But when the growth has increased in size and invaded adjacent structures, with, perhaps, the formation of secondary deposits, the operation for its removal becomes correspondingly difficult and the chances of freedom from recurrence correspondingly diminished. Whether the earliest stage of a suspicious growth is precancerous and its removal by operation preventive rather than curative is a point of theoretical rather than practical interest.

The causes of cancer being still, in spite of alleged discoveries of cancer germs, absolutely unknown there is no immediate probability of our being able to prevent the formation of growths which, whatever their primary characteristic, ultimately become malignant. What we can and ought to do, is to teach the laity to have removed at once every suspicious growth while its removal is easy and the risk of the operation practically *nil*, and in this way give the growth no chance of demonstrating its innocency or malignancy. If Mr. Keith will work on these lines he will find that he can afford to disregard "the cures in the daily papers" and will have "a really practical method of prevention," not of the formation of tumours but of the development of these tumours into growths which ultimately kill patients.

I am, Sirs, yours faithfully,

Plymouth, Jan. 1st, 1905. C. HAMILTON WHITEFORD.

OPERATIVE TREATMENT OF RESULTS OF CONSTIPATION.

To the Editors of THE LANCET.

SIRS,—Dr. A. G. Barrs in THE LANCET of Dec. 31st, 1904, p. 1888, asks Mr. W. A. Lane for an account of the ante-mortem and post-mortem observations upon which his description of the changes taking place in the intestine and its peritoneal coat is founded. As Mr. Lane's house surgeon I have had the opportunity during the past three months of seeing him operate on six cases of chronic constipation. In every instance the small intestine was dilated and flabby; in four I could distinctly see bands running upwards and outwards from a dilated colon; while in the other two I had not personally the opportunity of seeing or feeling the cæcum. On consulting my predecessors during the past year I find that they can recall 16 cases in which they saw similar adhesions about a dilated cæcum. I believe that very few post-mortem demonstrators make a thorough examination of the intestines and peritoneum *in situ*, so that it is not surprising that the effects of chronic constipation observed at these operations have not previously been described by pathologists.

I am, Sirs, yours faithfully,
Guy's Hospital, Dec. 31st, 1904. J. H. Clatworthy.

CANCER GENESIS.

To the Editors of The Lancet.

Sirs,—Referring to the letter upon this subject in your issue of Dec. 3rd, 1904 (p. 1613), the controversy was not of my seeking and at your request in my reply brevity will be aimed at. No attempt will be made to follow your correspondent in his remarks upon the University of Edinburgh or in his personal attack upon myself. He mentions that he sent me a copy of his book in July, 1902. This at once recalled the book and all about it to my memory. I read it upon its arrival and I knew where it stood in my bookshelves but I had failed to associate the name of your correspondent with the authorship of that book.

Perhaps by a few references to "The Principles" I may be able to demonstrate more clearly the nature of the divergences between us. On p. 66 the author writes: "But in the higher organisms certain cells never attain a high degree of development: they remain in a lowly organised condition, and serve, according as they are more or less unspecialised, either as germs for reproducing the entire individual, or for forming and maintaining the various tissues and organs. Such cells are found in all growing parts; they are the only real cancer and tumour germs." In the first place, if this be true, it would follow that a tumour could not be a twin homologous or identical with the individual containing it, but a new generation younger than the individual harbouring it and this is in direct contradiction with Mr. W. Roger Williams's main thesis. Secondly, while all reproductive or germ cells undoubtedly possess the potentiality of ultimately giving rise to new individuals as incidental products of their activities, it is only the unconscious memories of a certain few of them which lead to this attempt, while they inhabit as the home prepared for them the body of a higher animal, and the "germs for forming, &c." various tissues and organs do not exhibit this faculty in vertebrate animals and in all probability do not possess it. As little can it be maintained that "there is no fundamental distinction between the various modes of reproduction—sexual and asexual, &c." The whole of modern embryological and botanical opinion will be found to be in opposition to this conclusion, for it is not in accord with the facts of nature. Again, speaking of the relations of identical twins to double monsters, the author writes (p. 123): "Thus when the division of the undifferentiated embryo into two equal parts is complete, and each of these develops into a new being, homologous twins are the result; and this is the only instance of reproduction by gemmation in the highest animals." If identical twins arise in this way how do identical triplets come to pass? Does the "germ" here divide into three equal parts? If so, how does it contrive to do this and how do the conditions witnessed in certain armadillos, such as praopus hybridus, come about? Here, according to von Jhering, there are from four to 12 embryos produced from one egg, all of the like sex, all homologous or identical, and some of them more or less rudimentary. These are facts, not fables, for the discovery has been confirmed by Koelliker, and Sir William Turner has informed me that he himself has seen and worked upon them but that he has never published any of his finds. Is Mr. Williams or anyone else able to conceive that a "germ"—i.e., a blastoderm—can so "split" as to form 12 identical embryos? Why, moreover, are they all in the one trophoblast or chorion—a part of "the embryo" according to orthodox embryology—if this "splitting" have happened? If this be the explanation of all the above phenomena in the higher animals why can it not be applied to the lower ones and to plants? Do the medusæ of a hydroid polype arise by a "splitting" of a "germ" which in favourable circumstances might have given rise to one big medusa? Are the prothalli—the sexual generation—of a fern produced by splitting or does not each prothallus arise by the independent development of a single cell, here called a spore? Then there are the two kinds of identical twins—the rare "looking-glass-image" ones and the commoner sort "from the same mould." To which of the two does the explanation of the "splitting" apply and what cause lies at the bottom of the production of the other variety? "Splitting" will not account for both. The "looking-glass-image" twins are the greatest wonder in animate nature and the only possible scientific explanation of them is that they have arisen from the two products—right and left—of the division of a single cell; indeed, of an immediate forerunner of two primary germ cells. Elsewhere I have shown, and in the last two years no one has attacked the conclusion, that the primary germ cells of metazoan development (the formation of which demonstrably precedes the unfolding of an embryo and from one and only one of which "the embryo" takes its birth) are the equivalents of the spore mother cells of plants and that like the products of these, the spores, each primary germ cell has the potentiality of unfolding as an embryo. If two develop at the same time identical twins or double monsters result; if three, or eight, or 12, then the sequel is three, eight, or 12 identical embryos. Possibly the finds of so-called "experimental embryology" will be cited. This I define as "experimental pathology," for the results are either pathological or border on this science and in making his "Eingriff" the observer never knows, or can know, what he has really done.

The final examples to be cited from the "Principles" are the classification of the tumours based upon the now extinct "parablast" theory of His and the failure on the author's part to show what a malignant tumour really is, why it is malignant, and the passage to these from the teratomata. On the latter score nothing more need be said. Regarding the former, the "parablast" theory of His has long disappeared from embryology and even Professor His himself admitted its erroneous nature some few years before he died. Your correspondent is not the first medical man to make the mistake of seeing in my conclusions only another version of those of Weismann. If it be, indeed, Weismannism to deny most of the conclusions he has advanced in his "Vortraege," then, undoubtedly, I must be a very ardent upholder of Weismann's views. There are some slight differences. For example, Weismann maintains the "all-sufficiency" of natural selection, direct development, recapitulation in development, somatic origin of germ cells, a doctrine of heredity based on biophores, ids, idants, &c., germinal selection, panmixia, &c., *and all these things I deny, while with Weismann Mr. Williams advocates the first four.*

Whether my conclusions be "degenerate" or not they were at least founded on solid facts of observation, and they were not drawn without that "patiently worked-out story of the morphological continuity of the germplasm" (i.e., the germ cells) which Professor W. Osler, in the finest compliment my work has ever received, describes as "one of the fairy tales of science."[1] The facts concerning the wide and impassable gulf between somatic cells and germ cells are contained in my various memoirs: in Mr. Williams's book there is nothing of any scientific import regarding the origin and history of the germ cells. In the earlier part of his last letter to you he admits this but only to contradict it in the later portion. The doctrine of a somatic origin of germ cells was enunciated by Waldeyer in 1870. From then until 1900 on his observations alone it really rested. In 1902, after some of my work had appeared, he abandoned this view entirely and wrote: "The consequences of this doctrine of the continuity of germ cells are almost incalculable for every branch of biology." So that now the position of affairs is this, that there are no trustworthy observations whatever proving a somatic origin of germ cells in the higher animals. Moreover, in consequence of my finds such a somatic origin cannot be demonstrated, unless it also be proven that the germ cells were not in existence at earlier periods than those at which they were supposed to have arisen from somatic cells. It is not science to "believe" in a somatic origin when the main observations supposed to support this have been retracted, when the chief observations extant are opposed to it, and when there are no observations worthy the name upholding it. None the less, it may be many years before the myth completely disappears. Until then Professor Waldeyer will have repudiated his results in vain, for it will always be stated that he "proved" a somatic origin!

---

[1] W. Osler Science and Immortality, London, 1904, p. 58.

In his letters, as in his book, your correspondent provides excellent texts. Of course, "a single scale from the leaf or stem of a plant suffices for the reproduction of the whole organism." But the little finger of a man's hand or a bit of his skin has not this potency and there is no comparison possible between the asexual generation of plants, the sporophyte or flowering plant, and the sexual generation of animals, "the embryo" or individual. The conditions are, however, similar in the asexual generations of the two. Just as a single scale of a flowering plant may produce the whole individual plant, so also a small bit, even a single cell, of the trophoblast may on occasion give rise to ever more and more trophoblast, and the like is true of a malignant neoplasm. In all these instances we may witness unlimited powers of growth. This is why, for example, many of our choicest and commonest flowering plants owe their origin to a single individual plant which cannot with certainty be again produced from seed. This is why the investigators of the Imperial Cancer Research Fund were able from one fragment of a mouse tumour to "grow" ever so many pounds of cancer, transplanting other little bits to new ground. This is also one reason why cancer and sarcoma cells are never embryonic or somatic.

In my first article upon cancer in THE LANCET[2] there is in a footnote a rather long reference to the experimental researches of Driesch, E. B. Wilson, and others, who have followed in the footsteps of Roux. Is your correspondent aware that more recent investigators have considerably modified some of Roux's earlier results? Among his numerous observations Professor Roux has never recorded any work upon the origin and history of the germ cells of vertebrates. That he was the first to carry out certain experiments upon eggs in cleavage has no connexion with the question of the morphological continuity of germ cells or with that of the course of the life-cycle. In his former letter your correspondent had words of praise for Herbert Spencer; in his present one he strongly condemns him along with Weismann and myself. The association of my name, even in a damnatory sense, with the honoured ones of Weismann and Spencer, two good and faithful servants of mankind, cannot be other than complimentary, and it is herewith accepted as such a compliment. The future alone will decide the strength and stability of my "craft." I venture to believe that it may perchance weather all storms, for I know only too well what amount of hard, often midnight, work, unrequited by all else except results, it and its small cargo have cost.

I am, Sirs, yours faithfully,
Dec. 23rd, 1904. J. BEARD.

*** Dr. Beard's lecture, which originated this discussion, appeared in our columns on Oct. 29th, 1904, p. 1200. We have given now as much space to the controversy as we can afford.—ED. L.

HOSPITAL "ISOLATION."

To the Editors of THE LANCET.

SIRS,—In your issue of Dec. 17th, 1904, p. 1737, you make the following quotation from a communication received from Dr. F. Lucas Benham of Exeter, South Australia. "In THE LANCET of June 13th, 1896, you will find a letter from me on 'Isolation and the Public Health Act,' in which I think I anticipated even Mr. Marriott in contending that the necessity for public hospitals for infectious diseases was far from being proved. ...... In your issue of the following week (June 20th, 1896) Mr. Berry of Wigan wrote a letter in my support and not long after Mr. Marriott of Nottingham also entered the field on the same side." From this it would appear that I have usurped without the least acknowledgment the position of another. It happens, however, that I was in active opposition to the "isolation" craze 20 (or more) years ago and that many years before the appearance of Dr. Benham's letter (which it was my misfortune not to see) I was writing voluminously on the "isolation" question. Unfortunately, I have not any of these early communications in my possession but many of them were preserved by my distinguished friend Dr. C. Bell Taylor and are still available. It must be 25 years since the "Liverpool Committee" paid me a visit and took down my evidence *in re* the working of the local Notification Acts, which evidence was published verbatim in a report which is still extant.

To those who remember the days when the aggregation of *all* sick was regarded as a mistake to be remedied by the building of cottage hospitals the advancement of so self-evident a proposition as that the aggregation of the infective sick in large permanent hospitals must be bad will not appear to justify any considerable claim to honour and glory. Let us keep in mind the fact that nobody has ever yet explained the *raison d'être* of the aggregation hospital. The earliest experiment injured or killed everybody concerned with it, which made Sir Thomas Watson exclaim that but for a certain fact, now known to have been a fiction, these institutions which "concentrate the poison" were little else than a public danger. Later down the stream of time a chief inspector of the Local Government Board, Dr. Thorne, after having sung the praises of the "isolation" hospital to the Royal Commissioners on vaccination, was telling these Commissioners that he had made a great mistake and that the establishment of isolation hospitals at Leicester and Warrington had been accompanied by a marked increase in the scarlet fever attack rate. Since then sanitarians have been urging the municipalities all over the kingdom to build these hospitals without once telling them the reason why, and nobody knows or ever knew the reason why. The method of procedure was brilliantly illustrated recently at Lincoln. A few years ago this city was visited by an epidemic of—something. Dr. L.
who always approaches these
scientific spirit, was sent down f
Board to hold an inquiry. The inspector soon discovered that whatever it was he had to deal with it was not an epidemic of scarlet fever and that the trouble was not infectious. What happened? Lincoln forthwith broke out into an "isolation" hospital and only the other day his Grace the Bishop, surrounded by his *entourage*, was pouring out a libation to the gods because at last they could send the sick citizens to a place where if they had not got scarlet fever already they very soon would get it—and something else besides—and from which they would be able to return when convalescent to sow fever—and something else besides—broadcast in the interests of public health and as an object-lesson in preventive medicine. In conclusion, Sirs, I congratulate Dr. Benham on the fact that he contented himself with a letter in THE LANCET. Had he carried the thing further he might by this time have been the *mauvais sujet* of the public health profession. Instead of the peaceful life he is now living he would, having transgressed the sacred canons of that profession, have discovered that the way of transgressors is hard and that any stick is good enough to beat a medical reformer with.

I am, Sirs, yours faithfully,
Nottingham, Dec 24th, 1904. EDWD. DEAN MARRIOTT.

THE EVOLUTION OF MAN'S DIET.

To the Editors of THE LANCET.

SIRS,—I am not sure that Dr. Harry Campbell's general statements with regard to the digestion of cellulose have materially altered my views, but I venture to think that he has raised some points which would tend to support my position. Dr. Campbell brings forward the fact that a certain amount of chemical solution of cellulose takes place both in anthropoids and in man, but does not show that anthropoids are any more able to digest it efficiently than man by the agencies referred to. Cellulose "is remarkable for its great resistance to the most varied chemical reagents" and the digestion referred to is practically negligible, for the chief importance of cellulose in the diet lies in its inert and mechanical properties. Then, again, he suggests that the bitter and acrid taste of the food of anthropoids renders it quite unfit for human consumption. May we not suggest that these acrid and bitter tastes are the natural excitants of the salivary and other glands which have to do with the maceration and preparation of the cellulose? Moreover, if we at times were driven by hunger to eat such bitter foods might we not acquire the taste for them? Vegetable foods, especially fruits, very generally associate cellulose, sugars, acids, and acrid principles and it is scarcely right to consider the effects of any one of them when dissociated from the others. They naturally supplement each other. Thus while the cellulose on account of its physical nature is arrested in the mouth and disintegrated by the teeth the acids and acrid principles stimulate the flow of saliva and help to loosen the cellulose framework. Further, the acrid taste often remains in the mouth and continues to stimulate the flow of saliva even after the food has been swallowed. Then, again, the sugars stimulate the secretion of saliva, which further helps to macerate the cellulose. The mucous glands are likewise stimulated, and so the cellulose, and even any ligneous shreds which may accompany it, are coated with mucus and rendered fit for passage along the alimentary canal. Moreover, this copious secretion of saliva helps the more thoroughly to convert the starch and sugars, and the prolongation of the stage of alkaline digestion in the stomach has a certain importance in further disintegrating the cellulose.

---

[2] THE LANCET, June 21st, 1902, p. 1753.

It is not only on account of the effect on the cellulose that I would refer to the collateral benefits of bitter and acrid tastes. I would refer to them because the orthodox habit of giving young children almost nothing but soft, bland, *generally alkaline food has disastrous effects that are never* dreamt of. Thus, being for prolonged periods deprived of these bitter and acrid substances, when opportunity affords children very generally over-indulge in quite unripe and acrid fruits or acid drinks. If, however, the taste for bitter principles is allowed, or, better, *gradually stimulated* to develop, then such excesses are not indulged in. Similarly, a liberal supply of fresh ripe fruit helps to prevent the craving for, and excessive indulgence in, sugar or sweets. At first strongly acrid flavours, generally and advantageously, act as deterrants in the selection of foods but by experiment and by following the example of the parents the taste for these bitter principles becomes largely acquired. Frequent association of acrid with irritant principles, however, has naturally prevented a pronounced development of the instinct for bitter principles which, when fully developed, is somewhat antagonistic to the desire for sweets. The supply of sugar which was available for our ancestors was very limited and therefore prevented an excessive indulgence in it however strong the craving for it became. It is important to recognize this fact, not because the ruin of the teeth gives rise to many more serious troubles, nor because the injury to the teeth means ruin to the power to digest and relish some of the most luscious foods, but because it has become the fashion to belaud the dietetic value of sugar and to look upon it as an important food, while in reality it should be sparingly used and regarded rather as a condiment. What does it matter whether we can turn sugar into so many units of energy if at the same time it ruins the teeth and irritates the stomach to such an extent that healthy and vigorous digestion is lost? The use of condiments is a practical recognition of the value of bitter and acrid principles and a study of them reveals a philosophy which ought to influence our precepts with regard to the feeding of children.

It is, perhaps, impossible to estimate how far the capabilities of digesting or transmitting cellulose might be improved if the natural potentialities were allowed or stimulated to develop, instead of being suppressed and perverted. However, whether I have exaggerated our capabilities of transmitting cellulose or not, it is sufficient to find Dr. Campbell so distinctly enforcing our belief that "if physicians could be got to realise the importance of providing the jaws, teeth, and the muscular coats of the digestive tract with adequate work an untold amount of disease and suffering would be averted."

I am, Sirs, yours faithfully,

Wimpole street, W., Dec. 24th, 1904. J. Sim Wallace.

"WHO'S WHO" YEAR BOOK AND THE MEDICAL PROFESSION.

To the Editors of The Lancet.

Sirs,—My attention has been called to a list of "leading London specialists" in the above publication for 1905 in which my name has been included. I hope it is unnecessary to say that this has been done without my knowledge or consent. My object in writing is to point out how harmful to the public as well as to the profession the information thus afforded, imperfect and generally misleading as it is, must be. Although I understand that the publication of names in this way is not legally preventable, notice of the matter in the columns of The Lancet should go far towards avoiding a repetition of such a regrettable proceeding.

I am, Sirs, yours faithfully,

William H. Bennett.

Chesterfield street, Mayfair, W., Dec. 30th, 1904.

THE CAUSATION OF SEX.

To the Editors of The Lancet.

Sirs,—In The Lancet of Sept. 26th, 1891, p. 713, appeared a paper by Dr. Andrew Wilson of Edinburgh advancing a provisional theory of sex determination, according to which the causation of sex was primarily a matter of nutrition affecting the ovum at the time of fertilisation; that is to say, an ovum fertilised premenstrually, being stronger and more vital, tends towards the male side, while an ovum fertilised post-menstrually, having lost much of its vitality, tends towards the female side. In 1893 a further article appeared in your columns[1] giving illustrative cases in support of the theory.

Now, without having any bias in favour of this or any other theory it appeared to me that it would be a matter of interest to put it to the test of practice under conditions which absolutely precluded any source of error. This has been done with the following results:—

X., aged 28 years, married in 1897; previous menstrual history normal; no conception permitted for one year, during which menstruation was perfectly regular. Child I.: In 1898 a girl was desired. The last menstrual period ended on Feb. 6th, 1898; impregnation took place between Feb. 8th and 16th—i.e., was post-menstrual; confinement expected Nov. 13th; actual date of birth Nov. 14th; result a girl; subsequent menstruation regular. Child II.: A boy desired; last menstrual period ended Oct. 3rd, 1900; impregnation took place between Sept. 24th and Oct. 2nd—i.e., premenstrually; confinement expected July 10th, 1901; actual date of birth June 28th, 1901; result a boy; subsequent menstruation regular. Child III.: A girl desired; last menstrual period ended Feb. 27th, 1904; impregnation post-menstrual, between March 1st and 11th, 1904; confinement expected Dec. 4th, 1904; actual date of birth Dec. 2nd; result a girl.

In these three instances the result occurred as desired; conception was impossible at any other times than those stated, and in each case the prediction was communicated beforehand to a medical friend. No other children were born and no miscarriages occurred. The theory in question involves the assumption of a relationship between ovulation and menstruation which has, so far as I am aware, not yet been proved. The facts, so far as they go, lend support to the theory though the cases are, of course, too few to be of much value. To obtain precise and definite data on this question is a matter of considerable difficulty, and a few cases in which the facts are certain are worth many in which there may be some element of uncertainty. Hence my reason for recording them. If the theory be correct that sex is already determined in the ovum before impregnation takes place these instances of pre-determination must be regarded as pure coincidences; coincidences, however, which under the conditions of the experiment can only be characterised as striking. For obvious reasons I withhold my name but inclose my card and shall be happy to communicate through you, Sirs, with anyone desiring further information.

I am, Sirs, yours faithfully,

Medicus.

THE L.S.A. QUALIFICATION AND MEDICAL APPOINTMENTS.

To the Editors of The Lancet.

Sirs,—I am a member of a board which frequently has the duty of appointing a house surgeon and among the applicants we often have men holding the double qualification of the L.S.A. Lond. Almost invariably either a lay or medical member of the board will raise some objection to the L.S.A., mentioning that he thinks it an inferior qualification to the Conjoint Board of England, Scotland, and Ireland. Having employed men holding all the above qualifications and also university degree men I am quite of different opinion. Personally, I consider them perfectly equal to any ordinarily qualified man and anyone who takes the trouble to look up the examiners of the Apothecaries' Society of London will see that they are equal to any other examining board in the kingdom. As far as I know the report of the inspectors of the General Medical Council has always been satisfactory. I believe that the examiners in surgery are appointed by the General Medical Council themselves.

"NOT AN L.S.A."

Jan. 2nd, 1905.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Infirmary Poll.

IT may be remembered that the question of "beds or no beds" at the central receiving house to be built in connexion with the Manchester Infirmary was referred to a meeting of the trustees. At a meeting of that body held on Dec. 15th, 1904, a motion that accommodation should be provided near the Piccadilly site for the treatment of medical and surgical casualties and dispensary out-patients, for giving first aid, for the treatment of out-patients living at a distance from the new infirmary, and for the detention under observation for a few hours of cases of doubtful diagnosis was carried by a large majority. A poll, however, was demanded by those in favour of an amendment proposing that there should be "20 beds with all necessary equipment." The voting papers were issued on Dec. 17th and the returns were to be in by the 24th. The counting took place on the 28th. The number of voting papers issued was 1217. Of these 628 were returned. 335 were for the resolution (no beds) and 235 were for beds. Eight papers were spoiled. After all the agitation and excitement, the letters in the papers, and the strongly worded leading articles in newspapers in favour of the amendment, the number voting seems small. The opinion of the infirmary staff was, it is believed, unanimously in favour of the resolution and it was given expression to in some important letters from members of the staff which may have had more effect in guiding the opinion of the trustees than those from well-meaning laymen who were necessarily less conversant with the necessities of the case. Four or five years must elapse before the new hospital is ready and by that time it is believed that a greatly improved ambulance service will almost do away with the difficulties that some anticipate. After all, the distance from Piccadilly to Stanley-grove is not very great and the latter is conveniently situated for a very large population and time will most probably show that the fears now felt will prove to be groundless.

Reporting Cases of Anthrax.

A man employed by a firm of wool merchants at Bradford died on Christmas Day from anthrax and was buried on Dec. 27th. His employers reported the case to Mr. W. H. Seal, the chief inspector of factories for the district, and the medical attendant also did the same. The relatives submitted the medical man's certificate to the registrar of deaths who gave an order for burial and the body was buried. The registrar is reported to have said that there is [illegible] by-laws or in the general [illegible] communicate with the coroner [illegible] Bradford city coroner, it is reported, though he has the power, sees no reason why he should have the body exhumed. Mr. Seal is making his own inquiries. This occurrence is to be regretted. If the grave of a cow that has died from anthrax is a danger the same thing will be true of the grave of a man dead from the same cause and cremation is indicated rather than burial.

Vaccination Passive Resisters.

On Dec. 27th, 1904, a Mr. Smith returned to Great Harwood after serving 14 days in Preston Gaol for refusing to obey a vaccination order. He was welcomed by a brass band and a procession which went from the station to the British School where the pastor of the United Methodist Free Church presided over an indignation meeting. Mr. Smith was hailed, "not as a gaolbird, but as one who had the courage and manhood to suffer for conscience sake." In reply he said he believed "that the Vaccination Act, which was contrary to the spirit of equity and justice, would be removed from the statute book so soon as men showed that they preferred prison to compliance with its demands." A motion was carried pledging those present not to support those candidates for Parliament who would not advocate local option in vaccination. This wrong-headedness is becoming a serious and a very costly danger to the country.

"Schools or Nurseries?"

The medical officer of health of Burnley says that the infant schools there "are little more than nurseries," that teaching children three years old and under is a farce, and that their congregating together strongly disposes to the spread of measles and whooping-cough. He considers that the Board of Education cared little for infants of tender age or it would not pay for their attendance at school. "The school inspectors don't care and parents don't care; there is only the health committee of the corporation left to protect them." There is a good deal of truth in this indictment; the parents certainly regarding the infant school as a place where they can send their children for some hours a day and so be free for a while from the need of looking after them.

The Recent Fog.

Manchester shared in the visitation of fog which was recently so widely spread. The dangers of the streets, quite sufficient at ordinary times, were greatly increased. The discomfort to the eyes, the noses, and the lungs of healthy people was not merely annoying, it was often serious. And though it would be difficult to calculate the injury done to clothing and to all sorts of textile materials there is no doubt it is very great. In Manchester there was a sudden rise in the death-rate from 21·6 to 26·4 per 1000, an increase of over 22 per cent. Of these deaths 42·5 per cent. were due to diseases of the respiratory organs. Whatever may come of Sir Oliver Lodge's experiments in dealing electrically with fog all will agree with him that it is our primary duty to abolish smoke. As a leaderette in the *Manchester Guardian* of Dec. 29th, 1904, says, "the most fatal element in city fogs is that contributed by the smoke nuisance, which is preventable, and the deaths due to it must be regarded as deaths for which our apathetic and inadequate smoke policy is definitely to blame." Many of your readers may remember that at one of the Christmas shows of fat cattle in London some years ago several of these overfed but valuable beasts died as the direct effect of the fog and this object lesson produced some impression at the time. But it was soon forgotten. Of course, much of the extra mortality caused by the fog is not shown by the sudden rise in the death-rate but will be spread over some weeks. In this matter of prevention of smoke are we guilty of criminal negligence? For if we should sometimes have fog even without smoke it would have lost its sting and deaths directly due to it would be rare.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Exclusion of Young Children from School.

THERE appears to be a growing conviction among medical officers of health, medical officers of schools, and others who have given the subject consideration that the attendance of children under five years of age in public elementary schools is injurious to the mental and physical development of such children. In a paper read before the Childhood Society in March, 1902, and published in *Public Health*, vol. xiv., p. 570, Dr. Arthur Newsholme discussed the question very fully and maintained that such attendance "caused a heavy annual death-roll, and a large mass of sickness often leaving behind it permanent weakness and ill-health" and the Inter-[illegible] age and should be discouraged, if not absolutely prohibited, under five years. In October last the education committee of Newport (Mon.), on the recommendation of the medical officer of health (Dr. J. Howard-Jones), passed a resolution that, after the opening of the public elementary schools in Newport after the Christmas holidays no child under four years of age should be admitted or retained in the schools. In support of his recommendation Dr. Howard-Jones pointed out that the school attendance of infants as age periods when they are particularly liable to infection was undoubtedly responsible for the propagation of epidemic and consequently for a large proportion of preventable deaths and that it was of the greatest importance to postpone the period at which young children might be exposed to infection until they were of an age when certain diseases—e.g., measles—are not so fatal. The resolution of the education committee was brought to the notice of the Board of Education by His Majesty's inspector and the Board in a communication to the committee expressed the opinion that places should be provided in the public elementary schools for any children over three years of age whose parents desire to send them to school and, further, that it was undesirable for the committee to adopt a regulation excluding all children under four years of age from the schools. In support of its contention the Board reminds the committee that Section 1 (1) of the Elementary Education Act, 1891, provides for the payment of grants to local education authorities on account of the attendance at school of children over three years of age.

Death of Mr. Edward Treharne, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg.

The news of the sudden death from fatty degeneration of the heart of Mr. Edward Treharne of Barry on Dec. 29th, 1904, came as a great shock to the inhabitants of the district. Mr. Treharne was born in 1859 and shortly after taking the diplomas of the Royal Colleges of Physicians and Surgeons of Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow he began to practise in Barry, a town at that time increasing with remarkable rapidity. He was on the commission of the peace for the county of Glamorgan, a Freemason, and a prominent politician, having for some time been chairman of the Barry Conservative Association. He was also chairman of the Barry local board of health and later of the urban district council. He had a fine presence, was a noted athlete, and had played for Wales in international football. A widow and three children are left to mourn their loss.

Plymouth Borough Asylum.

Great progress has been made recently with the enlargement of the Plymouth Borough Asylum at Blackadon. The new wing for male patients will be completed within a month and the new wing for female patients by the end of March. The contract also provides for the addition of a storey to the old block of buildings. The electric light is being installed in all the buildings and a system of heating by hot-water pipes is being introduced. There are at present 276 patients in the asylum and by the enlargement accommodation will be provided for 200 more.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Glasgow Parish Council: Annual Report on Certification of Lunatics.

Mr. J. Carswell, certifying physician in lunacy to the Glasgow parish council, in his annual report for the year ending May 15th, 1904, states that there were 886 applications made to the inspector of poor on behalf of persons supposed to be insane. This number is 46 more than last year and is the highest in the history of the parish. But the number of applications bears no definite relation to the amount of certifiable insanity occurring in the parish, as is shown by the fact that the number of persons certified insane is less than in either of the last two years. There were certified insane 544 cases, as against 549 the previous year and 565 the year before. Of the 544 cases certified 164 had suffered from previous attacks of insanity; the remaining 380 represent the actual number of persons who became insane for the first time during the year. The actual number of first attacks certified this year is seven less than last year and the proportion per 100,000 of the population is 63·3, compared with 65·5 last year. This is the lowest production rate for four years. It is right to add that the estimated population upon which the rate is calculated is probably slightly higher than the actual population, because the city assessor's survey this year has shown an increase of uninhabited houses and consequently the population must be less than that estimated on the usual basis. Tables given reveal several facts of great significance, the most important of which are (*a*) that at all ages under 45 years insanity affects males and females almost equally; (*b*) that at all ages over 45 years more men become insane than women and both sexes become insane in larger proportion to the numbers living at these ages as they advance in years; and (*c*) that there is a relatively larger number of persons sent to asylums at ages over 45 years than under. The figures given in connexion with the last point are worthy of careful attention. The number of persons living in Glasgow parish at ages of 15 to 45 years is roughly 300,000 and they yield an annual average of 238 insane persons, or 8 per 10,000 of population; the number of persons living at ages over 45 years is under 100,000 and they yield an annual average of 128 insane persons, or slightly over 12 per 10,000 of population. But the difference in ratio is not only in degree but also in character; while the rate of 8 per 10,000 at the earlier ages is almost uniformly the same from year to year, the rate for the latter ages varies from a minimum of 11 to a maximum of 16 per 10,000. Clearly the ages above 45 years are not only more productive of insanity but there is an important difference in the manner in which the causes of insanity operate above and below 45 years. In his last annual report Mr. Carswell indicated the grounds upon which he based his opinion that economic and social considerations, which have but little to do with the causation of insanity viewed as a disease, account for the relatively larger number of persons who become pauper lunatics at the later ages in life and for the fluctuations in the production rate at those ages. But the ages from 15 to 45 years are the most important in relation to the question whether lunacy statistics indicate a process of mental deterioration going on in the community. These are the ages of greatest stress and temptation and they embrace the period of child-bearing. It cannot be said that a production rate of 8 per 10,000 relating to a section of the population numbering 300,000 is alarming. If the experience of the last four years is normal, as it appears to be, then we are justified in interpreting the steady production rate as meaning that so far as the masses of the people are concerned there is no evidence of an increasing mental deterioration. It is shown that there is no definite relation between the amount of lunacy and the death-rates, general and infantile. No doubt both the lunacy-rate and the death-rates are dependent upon two main factors—viz., inherent vital capacity and conditions of environment; but insanity is much more dependent upon the former than upon those physical and social conditions that affect the general and infantile death-rate. Speaking generally, it may be said that the greater the drunkenness of a community the greater will be its production of insanity. The figures given confirm that general view but they give no support to the exaggerated views that have been expressed in various quarters that lunacy caused by alcohol is seriously increasing in Scotland. The want of definite relationship between the number of public-houses in a district and the amount of lunacy is the counterpart of what evidently applies also to the relationship between the lunacy-rates and the death-rates and is open to the same explanation—viz., that in the causation of insanity the inherent tendency is of more importance than the conditions of environment. The number of persons treated in the observation wards during the year was 261, of whom 24 were afterwards removed to the asylum, 13 died, and 219 were discharged recovered or relieved, leaving five under treatment. This is the largest number treated and the largest number of recoveries. With the opening of the new psychiatric department at the Eastern District Hospital there will be a decided increase in the number of patients treated without recourse to the asylum.

Small-pox.

From Dec. 16th to 31st, 1904, inclusive the following 11 cases of small-pox were notified to the Local Government Board: from the Mull district, one; from the burgh of Dundee, three; from the burghs of Coatbridge and Glasgow respectively, one; from the Eastern district of Stirling, two and from the burgh of Falkirk, three.

Jan. 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Irish Population Statistics.

THE Irish Registrar-General has issued decennial summaries of the returns of marriages, births, deaths, and causes of death in Ireland for the years 1891–1900. The estimated population of Ireland has diminished to the extent of 249,455, or at the rate of 5·29 per cent., between the middle of the year 1890 and the middle of the year 1900, a decrease uninterrupted from year to year. The total number of births registered during the decade was 1,055,020, as compared with 1,150,463 for the previous ten years, being 95,443, or 8·3 per cent., less. The deaths during this decennium were 836,035, as compared with 883,156 for the previous ten years, showing a decrease of 5·3 per cent. but an increase in the average annual death-rate from 17·9 in the earlier to 18·2 per 1000 living in the later period. During the decade 433,526 emigrants, or 9·5 per 1000 of the mean population, left Ireland. The number of emigrants would thus appear to have surpassed the excess of births over deaths by 214,541. The number of emigrants in the preceding ten years was 770,706. There were 221,608 marriages during the ten years and during the past 40 years there has been a well-marked decrease in early marriages in Ireland. Judging by those who "signed their names in writing" as compared with those who signed "by mark," elementary education has made great progress; and it is curious to note that while in Ulster, Munster, and Connaught, taking the figures for each year of the decade, the married women seem to be better educated than the men, in Ulster the reverse was the case until the year 1900, when 85·5 per cent. of the men and 86·3 per cent. of the women signed their names in writing. There were 1,055,020 births registered in Ireland during this decade, of which 1,027,126, or 97·4 per cent., [illegible], or 2·6 per cent., were [illegible] the illegitimate births to the [illegible] greatest in Ulster where it reached 3·7 per cent., and least in Connaught, where it reached a percentage of only 0·6. It is also observed that in the rural districts of Ulster and Leinster the percentage of illegitimate births is only slightly below that in the urban districts, while in the other two provinces, where the rural population is more largely in excess of the town population than in either Leinster or Ulster, the difference between the rates in the civic and rural districts is more marked. 836,035 deaths were registered during the decade, and of these 86,231 were due to "specific febrile or zymotic diseases"—that is, 10·3 per cent. of all the deaths recorded. There were 235 deaths from small-pox (five deaths per annum in every 1,000,000 of the population), 4422 from scarlet fever (not a quarter of the mortality in the ten years ending with the year 1880), 1904 from typhus fever (a very great relative diminution), while typhoid fever caused 8692 deaths, which shows a slight increase on the previous ten years. Of these deaths 4142 occurred in Ulster. There were 12,048 deaths from whooping-cough and 3440 from diphtheria. Influenza caused 20,805 deaths, an enormous increase over former decades. There were 1601 deaths from intemperance, an increase being shown in the number of deaths of females due to chronic alcoholism. 24,435 deaths occurred from cancer; the increase is such that in the ten years 1891–1900 the registered mortality from cancer of persons 25 years old and upwards was 52 per cent. in excess of that for the ten years 1871–80 and 26 per cent. in excess of that for the ten years 1881–90. The highest county-rate mortality for cancer was in Armagh. The tuberculosis death-rate has risen in Ireland since the decade 1871–80, a fact which seems to show that the sanitary and other measures which have been undertaken for the improvement of the public health have not here arrested the ravages of this formidable disease.

Queen's College, Belfast.

Dr. W. St. C. Symmers of Cairo has been appointed Musgrave Professor of Pathology at Queen's College, Belfast.

Small-pox in Belfast.

There is no sign of decrease in the small-pox epidemic and the [illegible] ll that it may be necessary to [illegible] the 172 cases treated in it five [illegible], three were said to have been vaccinated in infancy, but the marks were very poor and indistinct, and no case whatever has been admitted where the patient had been revaccinated. Eight deaths have occurred and in each of the fatal cases the marks of vaccination, if present at all, were inefficient and in every case the disease was of a bad type and the eruption was confluent. Of these 172 cases admitted to Purdysburn Hospital since the beginning of the outbreak 130 have been discharged convalescent, eight have died, and 34 remain in hospital. In the reception house during the same period 552 persons were admitted. Of these, 445 have been discharged, leaving 44 still therein. At present a virulent type of measles is prevailing in Belfast and scarlet fever of a mild type is epidemic, but typhoid fever is much less prevalent. Between Nov. 20th and Dec. 17th, 1904, there were only 32 cases.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Strabismus.

AT the meeting of the Academy of Medicine held on Dec. 20th, 1904, M. Landolt read a paper on the above subject. After having reminded his audience that alterations in the mobility of the eye were a very frequent cause of visual troubles he showed that the usual operation for strabismus very often simply transforms a convergent strabismus into a divergent one. He proposed therefore to substitute for the usual operation one to which he has given the name of "muscular elongation"—i.e., he proposed to strengthen the weak muscle instead of weakening the strong one. Even in those very rare cases where muscular section or tenotomy can be carried out for extreme shortness of the muscle M. Landolt suggested a new operative procedure by which he preserves the point of attachment of the muscle and elongates it instead of transplanting the attachment further forward. In this way the action of the muscle after operation conforms more strictly to the normal than by the old operative method.

The Advantages and Disadvantages of "Dechloridation" in Epileptics.

At the meeting of the Hospitals Medical Society held on Dec. 18th M. Jules Voisin, M. Roger Voisin, and M. Krantz communicated the results of some researches carried out by them in 50 cases of epileptic adults and 28 cases of epileptic children. The results showed that a chloride-free diet did not by itself produce any modifications as to the epileptic attacks but that to bring about a favourable result the administration of bromide must be combined with the elimination of chloride from the diet. This method of treatment reduced the fits by 69 per cent. A chloride-free diet is difficult to carry out in these patients especially in adults and in these latter a peculiar kind of delirium is wont to occur signalised by melancholia with mental confusion and hallucinations. It arises from insufficient nourishment and possibly directly from the absence of salt. No signs of bromide poisoning were noted. T[illegible] alternations of a chloride-free [illegible] with a two months' period of [illegible] sidered that the physical and chemical phenomena which this method determines facilitate both the urinary excretion and the fixation of the bromide. Moreover, this method of a varied diet gives rise to full excretion and the complications of a chloride-free diet, which are often serious, are thus avoided.

Peroxide of Hydrogen in the Treatment of Infantile Dyspepsia.

Milk treated with peroxide of hydrogen in the proportion of one or two grammes of a 12 volume solution to 100 or 200 parts of milk seems to acquire properties comparable to those of kephir. It checks vomiting and diarrhœa and is readily taken by children. Peroxide of hydrogen acts in the stomach as a eupeptic and since it is a very powerful antiseptic it doubtless acts as such both in the stomach and in the intestines. These interesting results were communicated to the Therapeutical Society at a recent meeting by M. Gallois, M. Flourens, and M. Walter. In a general way gastro-intestinal antiseptics exercise an inhibitory influence not only on microbial ferments but also on the normal ferments of the organism. Peroxide of hydrogen is, however, both antiseptic and eupeptic. It is thus particularly indicated in cases of atonic dyspepsia accompanied by abnormal fermentation.

The Treatment of Sea Sickness by Hypnotic Suggestion.

At the meeting of the Society of Hypnology and Psychology held on Nov. 29th there was a most interesting discussion on the above subject. The first speaker was Mr. Hamilton Osgood of Boston. He cited his own case and told the meeting that on four voyages from England to America he had by suggestion prevented sea sickness. Not only had he not vomited but he had a good appetite and this immunity lasted throughout the voyage. M. Berillon suggested that persons liable to suffer from sea sickness who were never sure of finding a medical man on board who could practise hypnotism, should undergo suggestion before embarking. For his own part he had many times successfully suggested to a person during sleep a view of the crossing and the idea that he would not be ill. M. Farez had treated by hypnotic suggestion not only sea sickness but also carriage sickness and train sickness. M. Le Menant des Chesnais went even further. He cited the case of a lady whom he had hypnotised against train sickness. During his last holiday he was with her in a small boat, and a simple statement on his part that she would not be ill had sufficed to prevent sea sickness.

The Workmen's Compensation Act.

One point in this law which greatly concerns medical men has just been the subject [illegible] Minister of Justice. The circular [illegible] is a provision of the law laying down that in every case in which expert medical evidence is necessary the expert shall not be a medical man who has treated the patient or a medical man in the service of the contractor or the assurance society to which the contractor is affiliated. The Minister then adds that he has been informed that despite this provision certain of the magistrates are in the habit of summoning as an expert witness the medical man attached to the factory where the accident has taken place or to the assurance company which guarantees the owner of such factory. The Minister therefore begs to call the attention of magistrates to the above-mentioned provision and at the same time to remind them that the provision has reference to those cases in which the magistrates sit as judges to decide on the amount of daily compensation payable, as well as to those in which they sit with a view to decide upon cases of permanent incapacity when they simply have to examine the injured man under paragraph 3 of Article V. of the same law. This circular of the Minister of Justice remedies an abuse against which every medical syndicate has protested without ceasing.

The Academy of Medicine.

At the meeting held on Dec. 27th, 1904, M. Chamberland was elected as "*associé libre*" of the Academy of Medicine on the third ballot by 53 votes in room of the late lamented M. Duclaux.

Jan. 2nd

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Use of Adrenalin by Immigrants to conceal Trachoma.

THE Surgeon-General of the Public Health Service publishes reports of certain officers of that service to the effect that they have noticed for some time past on everting the eyelids of some immigrants that they presented a peculiar blanched appearance. At first it was thought that this was due to the treatment which they might have received prior to embarkation. Recently, however, several hours after the first inspection was completed and all suspicious cases had been set aside, it was decided to make a re-examination of the entire number. While this work was going on a number of additional cases of trachoma was found. Upon following some immigrants behind a convenient inclosure they were found to be busily engaged in instilling a substance into their eyes which subsequent investigation showed to be adrenalin. Experiments with this drug proved that if instilled into the eyes of mild cases of trachoma practically all evidence of the disease could be obliterated for about half an hour. It was learned that on arrival at port and just before the [illegible] made immigrants had been in the pra[illegible]alin into their eyes for the purpose of deceiving the inspector.

A Testimonial to Professor Osler.

The retirement of Professor Osler from the Johns Hopkins Hospital and School will be marked by the creation of a testimonial, as a recognition of distinguished services, by the profession and citizens of Baltimore. The proposition is so popular as to attract the attention of [illegible] movement bids fair now to become na[illegible] The governor of Maryland is to be the national treasurer. Upwards of $10,000 have already been subscribed. The form which this memorial shall take has been the subject of much discussion, but, on consultation with Professor Osler, it has been decided to erect a building for the accommodation of the valuable medical library of the medical and chirurgical faculty of Maryland, so largely the result of his own interest and effort.

Medical Service in the Panama Commission.

The United States Civil Service Commission has formulated its rules governing the appointments to the service of the Panama Commission. So [illegible] office [illegible] n the [illegible] tion. [illegible] are the chiefs of the divisions [illegible] ment of tropical diseases, will receive special credit. Only those who have had extensive hospital [illegible] familiar with the treatment of tropica[illegible] selected for appointment to the highest salaried positions. Promotions may be made in the discretion of the Isthmian Canal Commission from the lower to the higher positions in this grade. These examinations are open to all citizens of the United States who comply with the requirements. The term of service will be during the construction of the canal, which will extend throughout a period of eight or more years. Pharmacists, hospital interns, and trained nurses will also be appointed under similar rules after proper examinations.

Health of the Navy.

The Surgeon-General of the Navy reports that the health of the men was not as good as during the preceding year. The average strength of the active list during the year 1903 was 37,248. The total number of admissions for all causes was 28,569, the ratio per 1000 strength being 782·24, as compared with a ratio of 767·63 for the previous year, and 797·10 for the eight preceding years. There were 24,545 admissions for disease and 4024 for injury, giving ratios of 671·82 and 110·04 respectively. The daily average of patients was 1289·03 and the ratio per 1000 strength 35·23. The average of sick days for every man in the navy and marine corps was 12·88 and the average duration of treatment for each case was 16·49 days. The ratio of persons invalided [illegible] the year for disease and injury wa[illegible] disease and 5·18 for injury. Th[illegible]ber than those of the previous year, owing to the large number of recruits. The ratio of deaths during the year was 6·01 per 1000, being a ratio of 4·40 for disease and 1·60 for injuries. It is stated that venereal diseases continue greatly to impair the fighting strength of the navy. Excepting general infectious diseases venereal diseases gave a greater number of sick days than any other class. It appears that while the admissions to the sick list per 1000 of strength were greater than in the previous year the mortality was not only less but it was lower than the average of the past eight years. The Surgeon-General urges the importance of having trained women nurses as a part of the medical department of the navy. They would supply better and more efficient nursing to the sick and in the event of war the men could be released from hospital duty and assigned to vessels of war. The recommendation of [illegible]oyment of dentists for ser[illegible] The result of the experiment of treating consumptives in tents at Pensacola, Florida, in spite of many drawbacks, was so favourable that Congress is urged to make special provision for an appropriate site for a camp for tuberculous sailors.

Hospitals for Panama.

By a recent agreement between the United States and the Republic of Panama it is provided that the United States will construct, maintain, and conduct a hospital or hospitals either in the canal zone or in the territory of the Republic, at its option, for the treatment of persons insane or afflicted with the disease of leprosy, and any indigent sick, and the United States will accept for treatment therein such persons of these classes as the Republic may request but the order shall not be operative unless, first, the Republic of Panama shall furnish without cost the requisite lands for these purposes if the United States shall [illegible] hospital or hospitals in the territory of the [illegible]; secondly, that the Republic shall contribute and pay to the United States a reasonable daily per capita charge in respect of each patient entering upon the request of the Republic, to be fixed by the Secretary of War of the United States.

Unification of Medical Statistics.

The Surgeon-General of the United States army has issued in separate form the complete series of the tables of international military medical statistics. These tables were adopted at the meeting of the International Commission for the Unification of the Medical Statistics of Armies held at Budapest in 1894. They were somewhat modified at the meeting held at Madrid in 1904. 12 countries were parties to the agreement but only one other has published all the ten tables.

Dec. 24th, 1904.

Obituary.

FRANCIS HENRY BLAXALL, M.D. ST. AND., M.R.C.S. ENG., L.S.A.

FLEET SURGEON, R.N. (RETIRED); LATE MEDICAL INSPECTOR OF THE LOCAL GOVERNMENT BOARD.

Dr Francis Henry Blaxall, who died at his residence, Clan Lodge, Bathwick, Bath, on Dec. 23rd, 1904, was a public official with an admirable record for work who was personally known to two or three generations of medical men. Having become qualified as M.R.C.S. Eng. and L.S.A. as far back as 1847, he was appointed assistant surgeon in the Royal Navy in 1849, becoming staff surgeon in 1856 and fleet surgeon in 1869. Having then graduated in medicine at the University of St. Andrews, he served as assistant surgeon on H.M.S. *Colossus* in the Baltic during the Russian war and received for his [illegible] 1860-63, [illegible] rom the [illegible] *Urgent*, commanded by his friend Captain S. H. Henderson, which for three years was engaged almost continuously in trooping duties on the West Coast of Africa and in the West Indies under conditions which entailed a large amount of serious sickness and cast a heavy responsibility on the surgeon in charge. Blaxall made a notable contribution to the study of the great epidemic, termed at the time "malarious fever," which devastated Mauritius in 1867-68, killing some 43,000 persons (Royal Navy Report, 1867). He retired from the Royal Navy as fleet surgeon and when in 1871 the medical department of the Privy Council became merged in the Local Government Board, Blaxall, who had already worked for the Council under Simon's direction, became a medical inspector of the new Board. Buchanan, Ballard, Thorne-Thorne, and W. H. Power in those early days were among his fellow workers. As an inspector in the "seventies" Blaxall took an active [illegible] the administrat [illegible] by the Vaccin [illegible] largely occupie [illegible] sanitary districts [illegible] the administrati [illegible] which the Local Govern- [illegible] to shape on lines which [illegible] The principal means by which [illegible] e institution of a "sanitary [illegible] es in anticipation of cholera in the early "eighties." On this survey the bulk of the work in connexion with ports and shipping was organised and directed by Blaxall, with excellent results. Valuable reports on this subject were published in the medical officer's annual reports for 1886 and 1887. Another important inquiry, made by [illegible] aspects of emigration [illegible] United Kingdom and [illegible] place between home ports. Various investigations into local outbreaks of [illegible] o be referred to, as in certain of [illegible] much useful information as to [illegible] d diphtheria in their relation to [illegible]

Soon after his retirement from the Royal Navy, Blaxall married, in 1871, a daughter of Admiral J. G. McHardy.

It was formerly the custom of medical inspectors to live in provincial centres and Blaxall, whose work was mainly in the south-western and western counties, had his house and headquarters at Bath. Many public vaccinators and medical officers of health in those counties, and, indeed, almost all with whom he came into official relation, will recall with pleasure Blaxall's cheery and kindly personality and his help- [illegible] personal friendship and with conspicuous loyalty. For several winters before he retired from office Blaxall suffered from severe attacks of bronchitis and at the time of his retirement in 1891 his ill- [illegible] Treasury whic [illegible] by his long pe [illegible] the deduction of the retired naval pay to which he had long ago become entitled by independent service. Blaxall felt the injustice of this decision keenly; he fought the question strenuously and ultimately with success. As a result a principle was established by which many retired members of both services (including policemen, prison warders, and others in the humbler walks of life) have since been able to obtain equitable treatment. Blaxall possessed to a marked degree the openness, sincerity, and devotion to duty which are so often associated with the sailor and which in his case were combined with a kindliness and an unselfishness which endeared him to all. He never forgot his sea service and in later life took great pride in watching and assisting the progress of his many younger relatives and friends in the Royal Navy. Clan Lodge, his house in Bath, was always open—to be near Bath was of necessity to go to see Blaxall—and his kindly welcome there was always ready and not soon to be forgotten.

GEOFFREY EDWARD HALE, M.B., B.C. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.

THE death is announced of Dr. Geoffrey Hale of Eton. Like many of his professional brethren before him his life has been sacrificed in the pursuit of his duty. In attending a case of scarlet fever he contracted the disease and as a complication septic pneumonia from which he died on Dec. 31st, 1904, at the early age of 38 years. Dr. Hale, who was the son of the late Rev. E. Hale, known to so many generations of Etonians as a "dame," a mathematical and a science master, was educated at Eton and Cambridge and at St. George's Hospital. There he won a scholarship and held various house appointments, while at Cambridge he acted for some time as assistant demonstrator in anatomy and physiology. He was also honorary secretary to the Medical Officers of Schools' Association. He married in 1894 the eldest daughter of Canon H. Kynaston of Durham who was, under his former name of Snow, well known as an Eton master and tutor from 1858 to 1874.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. Curt Freidenberg, a Berlin gynæcologist.—Dr. J. C. van Aubel, formerly professor of pharmacodynamics and forensic medicine in the University of Liège.—Count Pietro Gradenigo, professor of clinical ophthalmology in the University of Padua.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At examinations for medical and surgical degrees held in Michaelmas term the following satisfied the examiners:—

FIRST EXAMINATION.

Part II., Elementary Biology.—P. B. M. Allan, and W. A. Anderson, Clare; [illegible] Bromley, Caius, J [illegible] Dellschaft, Jesus, [illegible] A. R. Hargreaves, [illegible] Christ's; G. Holm [illegible]

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Dr. Bruno Heymann has been recognised as *privat-docent* of Hygiene.—*Innsbruck:* Dr. Karl Mayer, Extraordinary Professor of Psychiatry and Nervous Diseases, has been promoted to an Ordinary Professorship.—*Jena:* Dr. Heinrich Eggeling, *privat-docent* of Anatomy and Prosector to the Anatomical Institute, has been promoted to an Extraordinary Professorship.—*Kieff:* Dr. G. Malkoff of St. Petersburg has been appointed to the chair of Internal Pathology and Therapeutics.—*Königsberg:* Dr. Hans Strehl has been recognised as *privat-docent* of Surgery.—*Seville:* Dr. Augusto Pi y Suñer has been appointed to the chair of Physiology.—*St. Petersburg (Military Medico-Chirurgical Academy):* Dr. V. Chagovetz has been recognised as *privat-docent* of Physiology.—*Strasburg:* Dr. A. Schwenkenbecher of Tübingen has been recognised as *privat-docent* of Internal Medicine.—*Vienna:* Dr. Johann Fein has been recognised as *privat-docent* of Laryngology and Rhinology.—*Warsaw:* Dr. Tikhanoff of St. Petersburg has been appointed Extraordinary Professor of Anatomy.

THE MOTOR MANIAC.—To drive a 14 h.p. motor-car through the streets of Lambeth on a wet night at such a high speed that witnesses are unable to read its number seems an unusual proceeding; to jump an excavation in the roadway nine feet long by four feet deep and four feet six inches wide, crashing through the surrounding poles and protecting lamps, is more remarkable; and for the car to proceed afterwards on its wild career at the same speed minus part of one hind wheel would appear incredible. All these feats of fancy "chauffeurship" were, however, performed by William Thomas on Dec. 10th last. We congratulate the public on the fact that Mr. Thomas was sentenced on Dec. 30th at Westminster police-court to two months in prison and the manufacturers of the car on the fine quality of their wheelwrights' work. The identification plate of the offender was not decipherable and he was only traced through his own employer who had reported the injuries of the car to the police.

RUSSIA'S APPRECIATION OF THE NOBEL PRIZE.—The patron of the Russian Imperial Institute of Experimental Medicine, Prince Alexander Petrovitch Oldenburg, gave a dinner on Dec. 23rd, 1904, in honour of Professor I. P. Pawlow, the principal of the physiological section of the institute, on the occasion of his having been awarded the Nobel prize for his distinguished scientific works. In the course of the evening the giver of the dinner, who presided, turned to Professor Pawlow and said: "I congratulate you on your having been awarded the Nobel prize. That great scientific victory gladdens not only the institute but all enlightened and thoughtful Russia." The guests numbered 40 and included many leading Russian scientific men.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.—The sum of £825 was collected in Plymouth on Hospital Sunday, Oct. 30th, 1904, and this amount has been handed over to the South Devon and East Cornwall Hospital in that city.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BARRETT, WILLIAM AMHERST HENRY, L.R.C.P. Lond., L.R.C.S. Edin., has been appointed Officer of Health to the borough of Newtown and Chilwell, Victoria, Australia, and to the shire of Meredith.

FISHER, WALTER, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Government Medical Officer and Vaccinator at Weston, New South Wales, Australia.

GAMBLE, MORRIS FREDERICK HORSLEY, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Deputy Medical Superintendent of the Metropolitan Lunatic Asylum, Kew, Victoria, Australia, during the absence on leave of Dr. Mullen.

GILL, J. MACDONALD, M.D. Lond., has been appointed Honorary Physician to the Royal Alexandra Hospital for Sick Children, Sydney, Australia.

HAY, A. G., M.D. Glasg., has been appointed Certifying Surgeon under the Factory Act for the Maryhill (Glasgow) District of the county of Lanark.

JAMIESON, J. W. M., M.B., Ch.B. St. And., has been appointed Physician to the Dundee Royal Infirmary.

JONES, P. SYDNEY, jun., M.B., Ch.B. Syd., has been appointed Honorary Surgeon to the New South Wales Deaf, Dumb and Blind Institute, Sydney, Australia.

SADLER, E. A., M.D. Lond., has been appointed Certifying Surgeon under the Factory Act for the Ashbourne and Mayfield District of the counties of Derby and Stafford.

STOKES, E. S., M.B., Ch.M., has been appointed Medical Officer and Bacteriologist to the Sydney Metropolitan Board of Water Supply and Sewerage.

TODD, J. N., M.B., Ch.B. Glasg., has been appointed Medical Officer to the Imperial Government Remount Depôt, Mooi River, Natal.

YOUNG, T. B., M.D. Brux., has been appointed Certifying Surgeon under the Factory Act for the Halesowen District of the county of Worcester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ARMY MEDICAL SERVICE, 68, Victoria street, London, S.W.—Examina- [illegible] ss than 25 commissions in the Royal [illegible]

[illegible] INFIRMARY AND CHILDREN'S HOS- [illegible] rgeon. Salary £120 per annum, with board, washing, and lodging.

[illegible] y Ophthalmic Surgeon. [illegible] SPITAL, Gray's Inn road, [illegible] Honorarium at rate of 40 [illegible]

[illegible] —Resident Medical Officer. [illegible]

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Anæsthetist. [illegible] Salary £100 per [illegible]

[illegible] SPENSARY.—Junior [illegible] nnum, with board, lodging, and washing.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Assistant House Surgeon Salary £60 per annum, with rooms, board, washing, and attendance.

DERBYSHIRE ROYAL INFIRMARY.—House Surgeon No. 2 and House Physician for 12 months. Salary in each case £100 per annum, with apartments, board, &c. Also Assistant House Surgeon for six months. Salary at rate of £60 per annum, with apartments, board, &c.

GROCERS' [illegible] for Sanitary Scienc [illegible] two years. [illegible] tant Medical [illegible] rd, lodging, [illegible]

[illegible] nd street, London, W.C.— [illegible] ualty Medical Officer, un- [illegible] h board and residence. [illegible] D WEST OF DISPENSARY.— [illegible] r annum, with residence, [illegible]

[illegible] Superintendent Salary [illegible] oard, lodging, and attendance.

NEW ZEALAND, UNIVERSITY OF OTAGO.—Professor of Physiology Salary £600, with half of class fees

NORFOLK AND NORWICH [illegible]

[illegible]

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory Act at Abingdon, in the county of Berks; at Alresford, in the county of Hants; at Kidwelly, in the county of Carmarthen; and at Peterborough, in the county of Northampton.

Births, Marriages, and Deaths.

BIRTH.

NORTON.—On Jan 1st, at Kennington Park-road, S.E., the wife of H Harvey Norton, L R C.P., M.R.C S, of a son.

MARRIAGE.

CARLING—COLEBROOK.—On Dec. 29th, 1904, at St. John Baptist Church, Kidmore End, Oxon, by the Rev. J. E. Smith Masters, assisted by the Rev. Canon W. W. Fowler, Henry Frank Carling, second son of William Rock Carling of Guildford, to Esther Lillie Colebrook, M.D., younger daughter of the late George William Colebrook of Reading.

DEATHS.

COPLEY.—On [illegible] mbs, William [illegible]

EDMONDS—C [illegible] Sanatorium, N. [illegible] the Rev. Her [illegible] late [illegible] R.P. Manchester Royal [illegible]

[illegible] Eton, Geoffrey, Edward [illegible]

[illegible] haw-street, St. Helens, [illegible] years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"CURE IN AN HOUR" BY RAZES.

Abou Bikr Mohammed Ibn Zakarya ar Razy, *usually known as Razes*, was one of the most illustrious physicians of the Arabian school and flourished in the tenth century, his death having taken place about A.D. 930 He is said to have been the author of some 200 works but it must be remembered that many treatises of Arabic medical writers are short ones, more of the nature of tracts than lengthy books. One of his most important works was upon Variola. Of his minor productions there is one entitled "Cure in an Hour" which has not hitherto been translated into a European language, though the Indian Mussulmans from time to time bring out very imperfect Arabic editions. Manuscripts of the work of more or less value are in the libraries of Paris, Berlin, Munich, Oxford, and Gotha, and there is an excellent one at Cairo. Dr. P. Guigues, professor at the Faculty of Medicine and Pharmacy at Beirut, possesses a valuable one also and there is a faulty copy in the library of the St. Joseph University at Beirut, useful, however, for collation with the Cairo text, because it is a member of the same family of codices Professor Guigues, who recently published a much larger Arabic medical work, "The Book of the Art of Treatment," by Najm Ad Dyn Mahmoud, with a valuable essay upon Arab pharmacy, has now translated into elegant French the little book of Razes, adding many valuable notes and giving a complete version of the Arabic as well (La Guérison en Une Heure par Razes, par le Dr. P. Guigues. Paris: Paul Geuthner, 10, Rue de Buci. 1904). In a kind of preface Razes presented an account of the reason which induced him to produce the work, which was that on one occasion the Vizir Abi-l Qassam Abdallah was discussing the question of disease and some of the disputants asserted that some illnesses, which resulted from the accumulation in the body of deleterious matter which before becoming manifestly injurious had been going on for days or even months, required in many cases days or months for their cure. But Razes added to the conversation that, on the other hand, there were some maladies which, if sufficient medical skill was attainable, could be cured in an hour. Thereupon the Vizir commanded him to produce a book stating what they were and the means for effecting their rapid cure Razes added in his prefatory note that it was his practice in his books to commence with the head and to discuss the various maladies until arriving at the feet and he would take the same course upon this occasion but as the diseases of some members, or parts of *the body, could not* be cured in an hour these would be passed over. The value of his treatise, it is better to state at the outset, is not so much, if at all, in the remedies which he proposes, as in the light that it throws upon the Arabic pharmacopœia, which is immensely enhanced by Professor Guigues's copious notes. It commences with headaches in the frontal region, for which Razes advises inhalation of Egyptian opium, that is, the juice extract of the papaver somniferum L. var. nigrum, obtained by incision of the capsules. He was, of course, recommending a comparatively pure [illegible] modern Egyptian variety. Another [illegible] seed. *He also advises a little* [illegible] it as he does not define their ingredients and as the varieties of them among the Arabs were very great it is useless to discuss these. The cause of headache in th central part of the cranium Razes attributes to excessive heat, [illegible] vinegar, and wine, [illegible] a concoction of [illegible] inegar. [illegible] the delphinium staphysagria of Linnæus, and also the sugar of another plant, the asclepias procera, *which was a discovery of Arabic herbalists.* The remedies for migraine are two first, fumigation with cyclamen or the bones of a dog If it is caused by facial paralysis barley-water, soaked barley mixed with gum ammoniac (dorema ammoniacum), and opopanax were to be prescribed. For epilepsy three plants, the cuscuta epithymum, the polypodium, and the lavandula stœchas, mixed with raisins, are promised to postpone any attack for a week. For epistaxis the insertion of alum in the nostrils is recommended and for hæmorrholds fumigation with arum and the internal administration of the same herb is stated to be most efficacious. Wounds are best healed by an *ointment consisting of lithocolle,* which was a [illegible]

[illegible] bases myrobolans, pepper, ginger, and so on A dose of the size of an almond might be taken at any time and by some persons daily, hence it was also called *the "Annual Electuary."* Razes, however, thinks a superior recipe is as follows. Citrullus colocynthis from which the skin is removed made into a suppository and so used will cure instantly unless the pain is very violent, in which case a handful of coriander, a little cumin and carum carui, and pomegranate seeds

A Clinical Lecture

ON

EMERGENCIES IN OPHTHALMIC PRACTICE.

Delivered at the Glasgow Ophthalmic Institution on Nov. 29th, 1904,

By A. MAITLAND RAMSAY, M.D. Glasg.,
F.F.P.S. Glasg.,

SURGEON TO THE OPHTHALMIC INSTITUTION, GLASGOW
ROYAL INFIRMARY.

Gentlemen,—The necessity for acting with promptness and decision in a case of emergency affords the best opportunity to test the power and resourcefulness of any man, and what is true of all is specially true of a medical man. At any hour of the night or day he may be summoned unexpectedly to attend an urgent case. Everyone in practice must remember with what trepidation he used to respond to such calls and how anxiously he wondered what the illness might be and what he would be able to do for the patient. After a time the exigencies of general practice make the medical man accustomed to such sudden demands upon his powers. He learns to wait and to see and in all circumstances he trusts to his experience for guidance; but even an experienced practitioner may feel anxious when he is called in haste to attend to some critical condition in connexion with the eye. When he arrives at the house the patient may be in great agony and both he and his relatives all much excited lest blindness or impaired vision is to be the result of the accident. Unless the medical man keep cool and collected, know well what he is about, and is possessed of a fair measure of common sense, he is prone to become infected by the atmosphere of nervousness around and to err in being either too optimistic or too pessimistic. In the former case, knowing nothing of the conditions, he may assure the patient that all will be right in a day or two and may thereby arouse hopes that can never be fulfilled. On the other hand, by being too pessimistic, he may, with equal ignorance of the case but perhaps more regard for his own reputation, occasion much needless suffering by giving a grave prognosis wh[illegible] might have been able to do m[illegible]ufferings and to quiet the alarm [illegible].

Unguarded expressions of medical opinion are always to be deprecated and can be avoided only when a case is approached with full professional knowledge and with the care that comes of deliberate consideration, for it must be admitted that want of care is just as common a cause of mistakes in practice as is want of knowledge. If a general practitioner does not feel confident in his own ability to make a thorough diagnosis he ought to have no hesitation in expressing a wish for aid by consultation; and when he is in doubt he ought never to accept the responsibility of advising the patient to wait for a few days on the chance that the difficulty will pass over. An opinion begotten of hope rather than based on experience is always baneful, for it lulls a patient into a false sense of security and does irremediable harm by allowing time to be wasted which fuller knowledge and larger experience might have used to effect a cure.

As it is to the family medical adviser that patients as a rule appeal in the first instance for aid, and as the fate of a damaged eye depends in most instances on the treatment first adopted, I propose in this lecture to try to offer some guidance as to the best methods of dealing with the commoner emergencies in ophthalmic practice. It is, of course, impossible to refer to every form of accident that may occur, for to do so would require a complete course of lectures on diseases and injuries of the eye. Personal experience, however, even though it be limited, is always of value and so I shall try to present in a connected form notes of some cases of emergency that have occurred in my own practice Before I do so, however, let me urge one important point. In the country emergencies are much more difficult to cope with than in towns because it is often impossible immediately to obtain many things that are absolutely necessary. Every country practitioner should, therefore, for the instant demands of ophthalmic cases, always carry with him an emergency supply and for this purpose a pocket set of ophthalmic discs will be found convenient.

When a wound implicates the margin of the eyelid the surgeon must be very careful to bring the edges accurately together with a suture, for if he neglects to do so it is likely that one or more cilia may become inverted and, scratching the cornea with every movement of the lids, prove a constant source of discomfort. If the injury be situated at the inner canthus there is a grave risk that the tear passages will be wounded and unless the condition be at once recognised and a road for the escape of the tears opened up complete obstruction will take place in the process of cicatrisation and the patient will suffer from persistent watery eye. These precautions appear obvious but they are often neglected, and what might have been a very trivial injury becomes through inefficient treatment at the outset a cause of great trouble and annoyance. Some time ago, for instance, I was consulted by a gentleman whose carriage had come into collision with an electric car and who had in consequence received from a piece of broken glass a slight wound at the inner canthus of the right eye. He was at once attended to by a medical man who applied a dressing to the injured part and in a couple of days healing was complete. The patient then, however, began to complain of watery eye, and more careful examination showed that the cut, tiny though it was, had severed the lower canaliculus and that the cicatrix had blocked the duct. There was a complete stricture and only after much difficulty was this overcome and the patency of the tear passages restored. Had the true nature of the condition been recognised at the time of the accident and the canaliculus slit up to the lacrymal sac the damage might have been repaired with the greatest ease.

It is a very common thing for the eyelids to be extensively lacerated by the fragments of a burst bottle or by the violence used in the course of an assault, and in all such injuries the surgeon ought to make it his first care to be sure that the globe itself is not implicated, for unless this be done the really serious part of the accident may be overlooked. That actually happened in the case of a man whom I saw in consultation some time ago. He was about to pull the cork from a bottle of soda-water when the bottle burst and the broken glass cut the left upper and lower eyelids very severely. He was at once attended by the family medical adviser and by another medical man who was called in the emergency. The wounds in the lids were carefully sutured and it was not discovered until a week later that there was a cut in the globe at its outer aspect behind the ciliary region. As the eyeball had by this time become infected all attempts to save it were unsuccessful; but had a thorough diagnosis been made at the time of the accident and had the medical men treated the ocular wound as skilfully as they did those of the lids the probability is that the eye would have been saved. In such circumstances it is often very difficult, on account of the extensive laceration, the swelling, the hæmorrhage, and the pain, to make a satisfactory and sufficient examination, and consequently if the surgeon has any doubt regarding the state of the eyeball he ought to administer an anæsthetic and not rest satisfied until he has obtained a complete view of the globe.

It often happens that, owing to the extreme sensitiveness of the structures implicated, an accident to the eye seems much more serious than it really is. Indeed, the pain and symptoms of distress are often in inverse proportion to the gravity of the injury. Here, again, it is very difficult to make a satisfactory examination, for the pain and intolerance of light set up blepharospasm so intense that it is almost impossible to separate the lids. The accident often occurs in the simplest manner possible. A lady while dressing her hair strikes the cornea with the brush or the curling tongs, a gentleman is lighting a cigar when a spark flies from the head of the match and enters the conjunctival sac, or a nurse is playing with an infant and receives a scratch on the eye from the baby's finger nail. These are only a few examples from many that might be cited. In nearly every case the patient believes that serious damage has been done. He speaks of the pain as agony and is quite unable to open the eyelids. As a rule, however, a few applications of a 2 per cent. solution of cocaine overcome the surface irritability and permit the surgeon to separate the lids and to examine the cornea. A small abrasion is usually detected and if this be treated by an antiseptic lotion, an ointment containing cocaine, and a compress and bandage healing takes place rapidly. If, however, the breach of surface becomes infected by micro-organisms from the conjunctival sac, the edges of the lids, or the larcrymal passages, suppuration ensues, and what was, to begin with, a very insignificant injury becomes serious and a grave menace to sight. It must never be forgotten that no injury to the eye is so trivial that it can with safety be neglected or so insignificant as not to require the most skilful treatment.

Of all injuries to the conjunctiva none is more disastrous in its results than a burn, especially one due to the action of any chemical irritant, such as quicklime or sulphuric acid. In all cases of this kind the prognosis must be very guarded as the action of the chemical extends far beyond its point of application, and what seems at first sight only to have caused a greyish haze over a part of the surface of the cornea will probably by the end of a fortnight have brought about the total destruction of that membrane. It may be noted, however, that very severe causes do not always produce proportionately severe results. When molten metal, for instance, gets into the eye it might be expected to cause, and very often does cause, serious structural damage; and yet, on the other hand, there are cases in which the injury is remarkably slight. The explanation is that on the first entrance of the metal the great heat makes the moisture in the eye pass into what physicists call its "spheroidal state" and the spheroids of water, acting as a non-conductor, protect the eye from injury. In all severe burns both ocular and palpebral mucous membranes are destroyed and as the raw surfaces adhere to each other in the process of healing the eyelid becomes firmly fixed to the eyeball. This condition, which is known as symblepharon, will, no matter how much care is taken to prevent it, certainly occur in every case where the retro-tarsal fold of conjunctiva has been destroyed. If it be extensive, it not only interferes with vision but also causes intolerable discomfort from the sense of dragging which it produces. After an eye has been burned the conjunctival sac ought thoroughly to be irrigated with any bland fluid, and afterwards a few drops of cocaine dissolved in castor oil instilled, or preferably a 5 per cent. solution of chloretone in olive oil. An iced compress should be laid over the closed eyelids and the patient put to bed. In order to combat the inflammatory reaction which is sure to follow, the ice-cold compress should be continued for at least 12 hours and saline purgatives administered, while the pain must be subdued by the application of leeches and by the hypodermic injection of morphine in the temple. The use of anodynes has the additional advantage of inducing sleep and soothing the nervous system generally.

After a blow from a cork suddenly expelled from an aerated-water or champagne bottle there are always subconjunctival hæmorrhage and, if the contusion has been severe, more or less dimness of vision. The pupil is, at first, somewhat contracted and does not readily yield to the action of atropine, which may have to be instilled several times before full dilatation is produced. The pupil often expands irregularly, assuming an oval shape before becoming round. Unless the eyeball has received some structural damage the dimness of sight, which is supposed to be due to shock sustained by the retina at the time of the accident, is always transitory and often of very short duration. Intra-ocular hæmorrhage is of frequent occurrence after contusions of the eyeball, even in cases where there is no evidence of rupture of any portion of the uveal tract. The effused blood may appear in either the aqueous or the vitreous chamber; it always interferes with sight and produces a peculiar discolouration of the iris and sometimes patients complain that when they look at a light it seems to be red in colour. The delicate and sensitive tissues of the eye are very intolerant of sharp sudden blows and many eyes have been lost after such an apparently simple injury as that caused by the rebound of a twig of a tree, the flapping of a sail, or a stroke from a whip-lash. Such injuries may be followed by rapid loss of sight and by inflammation so severe and persistent as to terminate in atrophy of the eyeball. It is wise, therefore, always to adopt antiphlogistic treatment from the outset and after instilling atropine to apply leeches to the outer canthus and iced cloths to the closed eyelids, to administer a sharp purge, and to confine the patient to bed. An ophthalmoscopic examination should be made as soon as possible, because structural damage—hæmorrhage from the retinal and choroidal vessels, detachment of the retina, rupture of the iris or choroid, or dislocation of the lens—is not infrequent, and in view of possible legal proceedings in connexion with claims for compensation it is well to know of its existence without unnecessary delay.

Subconjunctival hæmorrhage may sometimes take place spontaneously and as the effused blood is readily seen the state of matters appears much worse than it actually is and always excites much alarm. In children it is not infrequent during an attack of whooping-cough and in adults it occasionally follows coughing, vomiting, or any violent exertion. As a rule, it is of very little significance and disappears completely in about a fortnight. It is always wise, however, before offering any definite opinion, to make an ophthalmoscopic examination, and, in the elderly especially, to take the additional precaution of examining the urine. It occasionally happens that after an accident a patient discovers, for the first time, that the sight of one eye is defective. He naturally attributes this to the injury, although it may be the result of congenital deficiency and may have been present all his life; consequently, the medical attendant must always be fully alive, not only to this possibility, but also to the fact that for the purpose of pecuniary gain the patient may be either exaggerating his symptoms or actually malingering.

When the injury has been so severe as to produce fracture of the bones at the inner side of the orbit, communication is opened up with the frontal and ethmoidal sinuses and air is thereby allowed to escape into the surrounding cellular tissue. This is known as emphysema of the eyelids. It is usually accompanied by epistaxis and the soft swelling is readily distinguished by crackling to the touch and increasing rapidly in size when the patient blows his nose. Here a firmly applied bandage is an essential part of the treatment. Again the bones of the orbit may be fractured without implication of the air sinuses and although externally there may be nothing visible except what is usually called a "black eye," yet the patient may not be able to distinguish light from darkness. In these circumstances it is likely that the optic nerve has been injured and although ophthalmoscopic examination shows at first little abnormal, yet sooner or later it will reveal all the signs of complete atrophy of the optic disc. After such an accident, therefore, the prognosis must always be guarded until sufficient time has elapsed to permit the case to declare itself fully.

The practitioner may, however, be called to attend a case of sudden blindness in which there is no history of injury. Here is an example. A girl, 17 years of age, came home from work apparently in her usual health and without pain or forewarning of any kind, while she was cutting bread for supper, she experienced a sensation as if a cloud had passed before her right eye and on looking up and closing the left she found that the eye affected was so blind that she was quite unable to distinguish light. A condition like this is in all probability permanent and the result of embolism of the central artery of the retina, so that the medical man must be on his guard not to misinterpret its significance and to confuse it with the transitory blindness which occasionally precedes sick headache or the dim vision which may be premonitory of glaucoma. He ought always to investigate the history of the case carefully, and roughly with his hand to map out the field of vision so as to determine whether the retina is wholly or only partially involved. In that way he may be able to arrive at some notion as to the probable cause of the defective sight—intra-ocular hæmorrhage, retrobulbar neuritis, detachment of the retina, &c.—but before committing himself to any definite opinion he should make a careful study of the results of ophthalmoscopic examination and if he be unable to use the ophthalmoscope himself he ought never to delay in obtaining the assistance of an expert.

In all those cases of sudden blindness to which I have just referred the patient, as a rule, never complains of pain, nor is there any sign of inflammation in the eyes themselves. It is, however, quite otherwise with the condition which I am now about to describe. Here also the onset of the failure of sight is sudden—often alarmingly so—but it is accompanied by agonising pain and intense inflammation. The onset of the symptoms frequently occurs during the night and is accompanied by bilious vomiting and perhaps purging. The danger is that the pronounced symptoms so common as accompaniments of an ordinary bilious attack may deceive the practitioner and draw away his attention from the real seat of trouble—the eyes. The patient himself may add to the misapprehension, for he naturally connects the pain in the head with the vomiting and attributes the failure of sight to the biliousness. In such a case one point is worthy of special notice, as it is always most helpful in the diagnosis. If the patient be questioned and should describe the eyeballs as feeling swollen almost to bursting and too large for the sockets, it is well to consider at once whether or not the case is one of acute [illegible] man should therefore take imme- [illegible] the globes to ascertain the state [illegible] Almost invariably the eyes will be found of stony hardness. There will be extreme congestion and œdema of the ocular conjunctiva, the pupil will be dilated, and the anterior chamber shallow. Let him be on his guard also not to misinterpret the significance of this form of ocular inflammation, for to do so is fatal. The dilated pupil and shallow anterior chamber, associated with the stony hardness of the eyeballs, are unmistakeably characteristic and ought to prevent glaucoma from ever being mistaken for iritis. Unfortunately, however, while that is so, such a mistake is far too common, and as the treatment for the one is exactly the opposite of that for the other the error is a very serious one. Atropine is instilled with the result that the symptoms are aggravated and the patient's chances of recovering sight are materially lessened. Whenever the practitioner satisfies himself that the case is one of glaucoma he ought at once to instil eserine, to put leeches to the temples, and to apply fomentations to the eyes. If in a few hours the pain has not subsided means must be taken to reduce intra-ocular tension by opening the eyeball so as to relieve the strangulation at the corneo-iritic angle. If the practitioner cannot obtain assistance he ought not to wait but should at once puncture the sclerotic with a narrow knife and allow some of the vitreous to escape. If he observes strict antiseptic precautions this can be done without danger and will give relief till the services of a specialist can be obtained. If the increased tension be not lowered impaired sight or even blindness will almost inevitably result but the hopelessness of the condition is at once removed by the performance of iridectomy. The all-important thing is that the case be taken in time.

In every instance that I have cited the ability to make an early and accurate diagnosis is a matter of the first importance. Delay is always dangerous and the patient's chances of a favourable result depend upon prompt and skilful treatment. It is true that an error in diagnosis may sometimes be rectified in time to prevent the patient suffering any serious damage but in acute glaucoma, if sight is to be preserved, surgical interference must take place as soon as possible after the disease has declared itself. Here the damage done by delay is irretrievable and all regrets are vain.

THE X RAY TREATMENT OF LEUKÆMIA.

REPORT OF A CASE, WITH AN ABSTRACT OF THE LITERATURE.

BY J. C. G. LEDINGHAM, M.A., M.B., B.Sc. ABERD.,
CARNEGIE FELLOW IN PATHOLOGY; LATE ANDERSON SCHOLAR,
UNIVERSITY OF ABERDEEN;

AND

R. G. McKERRON, M.A., M.D. ABERD.,
SENIOR PHYSICIAN TO THE ROYAL HOSPITAL FOR SICK CHILDREN,
ABERDEEN.

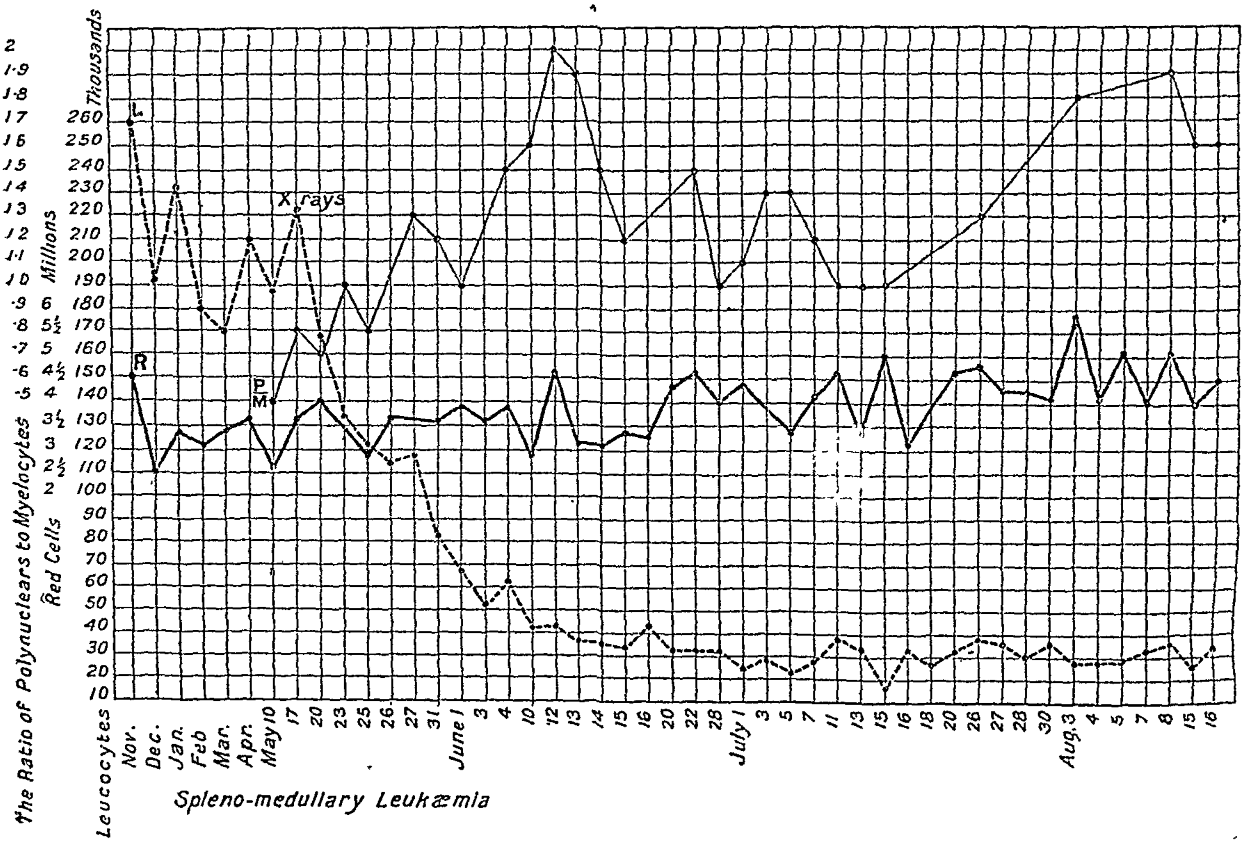
IN the *Medical Record* of August 22nd, 1903, there appeared an article by Nicholas Senn entitled "A Case of Splenomedullary Leukæmia successfully treated by the Use of the Röntgen Ray." The notes of this case were briefly as follows. The patient was a married female, aged 29 years, who for a year previous to admission to hospital had experienced sharp pains at varying intervals in the left hypochondriac region. Her abdomen had noticeably increased in size and over the epiphyseal extremities of the long bones and sternum dull aching pains were frequently felt. On admission in January, 1903, the spleen extended nearly to the pubes and two inches beyond the median line on a level with the umbilicus. It was tender on deep pressure. The liver was palpable below the costal arch. The urine amounted to 1200 cubic centimetres; it had a specific gravity 1015 and contained a trace of albumin. Slight cough was present. There were no tubercle bacilli in the sputum. The temperature varied from normal to 100° F., with a slight rise noticeable towards evening. The slightest exertion caused shortness of breath and rapid pulse. Blaud's pills and Fowler's solution were prescribed and continued for three weeks without making any impression. Three weeks after admission the x rays were applied over the spleen, sternum, and epiphyseal extremities of the long bones daily for from ten to 20 minutes. At the commencement of this treatment a blood examination showed: red cells, 3,500,000 per cubic millimetre; white cells (chiefly myelocytes and eosinophiles), 648,000 per cubic millimetre (no differential count recorded). Pronounced poikilocytosis was present. During the course of treatment the use of the x rays had to be suspended for a day or two on several occasions owing to the occurrence of high temperature and other symptoms of intoxication. Three weeks after the commencement of the treatment indications of progressive decrease in size of the splenic tumour were noted. The blood was examined at intervals of a few days and it was noticed that improvements in the condition of the blood kept pace with reduction in the splenic volume. The first decided changes were the gradual disappearance of the myelocytes and eosinophiles and the return of the erythrocytes to their normal shape. On April 12th the blood showed no myelocytes, only a very few eosinophiles, and very little poikilocytosis. The patient left the hospital but returned daily to the out-patient department for x ray treatment. Menstruation returned at regular intervals and the last blood examination showed no abnormalities in structure or in the relative numbers of red corpuscles and leucocytes. Senn attributes the result to prolonged use of the Roentgen rays.

In the *Medical Record* of April 9th, 1904, appeared an article by Bryant and Crane, entitled "Two Cases of Splenomedullary Leukæmia; Treatment and Recovery." The first case was that of a woman, aged 33 years, who was admitted to hospital on Sept. 29th, 1903. On admission the spleen extended two inches to the right of the umbilicus and three inches below it; it filled two-thirds of the abdomen. Examination of the blood gave the following result: red cells, 3,500,000 per cubic millimetre; hæmoglobin, 50 per cent.; and white cells, 176,000 per cubic millimetre. Myelocytes predominated and eosinophiles were increased; [illegible] present. [illegible] and the [illegible] ends of the long bones for ten minutes on every second day. On Oct. 12th the blood count gave the following result: red cells, 4,000,000 per cubic millimetre; hæmoglobin, 60 per cent.; and white cells, 55,700 per cubic millimetre. Myelocytes were diminished and polynuclear cells predominated. The x ray treatment was suspended from Oct. 12th to 25th owing to its causing nausea, headache, and nervousness, with cardiac palpitation. On Nov. 1st the blood was again examined with the following result: red cells, 5,000,000 per cubic millimetre; white cells, 4500 per cubic millimetre; and hæmoglobin, 60 per cent. The white cells were in normal proportions. Nucleated red cells were absent and the spleen was of normal size. The pain in the long bones had disappeared. On the 16th the blood was normal and the spleen extended a little below the twelfth rib. On the 27th the patient felt quite well. Her appetite was excellent and she felt better than she had done for years.

The second case was that of a male, aged 31 years, who was admitted to hospital on Feb. 16th, 1903. Enlargement of the abdomen had been noticed since 1899. The spleen extended into the pelvis. Examination of the blood gave the followin [illegible] metre; and [illegible] myelocytes. [illegible] doses, with bone marrow and iron. On August 1st the splenic tumour was noticed to be disappearing. On Oct. 12th the hæmoglobin was 80 per cent.; the red cells were 5,300,000 per cubic millimetre; and the white cells were 6400 per cubic millimetre. A differential count showed normal proportions. The splenic tumour had entirely disappeared.

Bryant and Crane state that the x ray treatment hastened matters in the first case. The woman had been under treatment but a very few days when there was noticeable diminution in the size of the spleen, followed by a severe constitutional reaction. The second case (with no x ray treatment) improved slowly with no marked disturbance, but the tumour did not begin to disappear till three or four months after the beginning of the treatment.

A remarkable article by H. Heinecke on the effect of the x rays on the internal organs appeared in the *Münchener Medicinische Wochenschrift* of May 3rd, 1904. He found that small animals exposed to the rays for a number of hours died in from seven to 14 days. The spleen showed an excessive increase in the pigment, disappearance of follicles, and destruction of the splenic pulp. A large number of animals of about the same size were then exposed to the x rays and it was found possible to separate entirely the processes in the follicles from those taking place in other parts of the spleen. The former started a few hours after beginning the radiations and were completed in 24 hours. The nuclei of the lymphocytes in the follicles disintegrated within a few hours and the remnants were taken up by the phagocytes which shortly disappeared from the spleen. This resulted in an almost complete destruction of the follicle. Analogous processes took place in all other lymphoid structures of the body and in the marrow. It was determined that the minimum length of time required to bring about these changes was 15 minutes in rabbits or a moderate-sized dog. Heinecke believes that similar effects take place in man and that the lymphoid structures are affected without there being any marked reaction in the skin. He therefore claims that a therapeutic application may be made of this principle in treating certain diseases of the lymphatic system, leukæmia, pseudo-leukæmia, and lympho-sarcomata. He also refers to cases treated in this way by American surgeons. The results obtained by the authors above quoted in the treatment of leukæmia and by Heinecke in his experiments on animals led us to believe that at any rate x ray treatment was worth a fair trial where other therapeutic measures had failed to make any impression.



Blood chart before and after the commencement of radio-therapy on May 17th, 1904.

In the medical wards of the Royal Hospital for Sick Children, Aberdeen, there happened to be a boy suffering from spleno-medullary leukæmia, with enormous enlargement of the spleen and a characteristic blood picture but whose general condition was otherwise so satisfactory as to render him an eminently suitable subject for treatment by the x rays. The following are brief notes of the case up to the point when x ray treatment was determined upon.

The patient, aged 11 years, was admitted on Nov. 19th, 1902. He was emaciated and weak but did not present any obvious signs of anæmia. There was marked distension of the abdomen, due to an enormous enlargement of the spleen, the lower border of which reached to within a finger's breadth of the pubes, while the anterior border extended two inches beyond the middle line. Examination of the blood showed the characteristic changes of leucocythæmia of the spleno-medullary type—red cells, 3,570,000 per cubic millimetre; white cells, 234,000 per cubic millimetre; and hæmoglobin, 80 per cent. Myelocytes were numerous but no differential count was recorded at this date. For a few days after admission the temperature rose in the evening to from 100° to 101° F. It then became normal, probably as the result of complete rest in bed, and continued so for several weeks. The boy was allowed up; this was at once followed by a return of the pyrexia, the evening temperature reaching from 102° to 103°, and on every subsequent occasion on which he was permitted to get up a similar rise of temperature with deterioration of the general condition was observed. Apart from these elevations of temperature, there were intermittent attacks of pyrexia for which no explanation could be found. The treatment consisted chiefly in rest and dieting. Arsenic in small doses was prescribed but was so badly borne that it had to be discontinued. For the one and a half years in which he was in the wards previously to the commencement of the x ray treatment there was little change in the boy's general condition. The spleen perceptibly increased in size but the blood, though the counts varied considerably, did not show any progressive deterioration.

Treatment with the x rays was begun on May 17th, 1904. During the preceding six months examinations of the blood were made at frequent intervals and it was found that the white cells oscillated round a mean of 200,000 per cubic millimetre, with variations of 40,000 on either side, while the red cells averaged 3,300,000 per cubic millimetre, the ratio of white to red remaining at the fairly constant figure of 1 to 15. As has been frequently noted in leukæmia the daily variations of the white cells were considerable, amounting in this case to 50,000 on several occasions. But a point to which sufficient attention has not been drawn is the remarkable and unaccountable variation in the number of red cells from day to day; a drop of 500,000 or even 1,000,000 within such a short interval as two days was quite a marked feature, and it is to be noted that treatment of a therapeutic nature could have played no part in bringing about such changes, for no therapeutic treatment of any kind was employed. The hæmoglobin percentage, as ascertained by Haldane's instrument, remained fairly constant, about 55 per cent. A few differential counts are appended showing the condition of the blood in the six months previous to the x ray treatment. On Nov. 7th, 1903, examination of the blood gave the following result: red cells, 4,056,000 per cubic millimetre; white cells, 260,800 per cubic millimetre; myelocytes, 48 per cent.; polymorphonuclears, 39 per cent.; small and large lymphocytes, 8 per cent.; mast cells, 6 per cent.; and nucleated red cells, 4 per 100 white cells. On March 24th, 1904, the blood count was as follows: white cells, 236,800 per cubic millimetre; myelocytes, 56 per cent.; small lymphocytes, 5 per cent.; large lymphocytes, 12 per cent.; polymorphonuclears, 18 per cent.; ordinary eosinophiles, 8·9 per cent.; and normoblasts, 3 per 100 white cells. On May 10th, exactly a week before the commencement of the x ray treatment, a blood examination showed: red cells, 2,560,000 per cubic millimetre; white cells, 188,000 per cubic millimetre; io of white to red cells the leucocytes gave th es, 9 per cent.; large lymphocytes, 12 per cent.; large hyaline leucocytes, *nil;* neutrophile myelocytes, 44 per cent.; coarsely granular eosinophile myelocytes, 1 per cent.; finely granular eosinophile myelocytes, 1 per cent.; polymorphonuclears, 22 per cent.; ordinary eosinophiles, *nil;* mast cells, 8 per cent.; and nucleated red cells, 8 per 100 white cells. The ratio of polynuclears to myelocytes was 0·5, the myelocytes predominating largely, as was the case in all the counts made during the previous six months.

Following Senn's method, the x rays were applied over the splenic tumour and the lower epiphyses of the femora. Occasionally also they were applied over the sternum and vertebræ. The exposures lasted from ten to 15 minutes every alternate day, but for a period an exposure was given every day with no bad effects. In fact, throughout the three months of x ray treatment no constitutional effects were noted at all apart from slight prickling sensations lasting for a short time after the applications. There was never any nausea, headache, or rise of temperature traceable to the x ray treatment. In this respect this case differed considerably from Senn's and Bryant and Crane's cases. It must be noted, however, that during the week June 12th to 18th a marked erythema appeared over the splenic area which had been exposed to the rays. (N.B.—The vacuum tube was always fixed at a distance of somewhat over five inches from the area exposed.) The part did not itch, nor did it cause the patient any inconvenience, but it was considered advisable to discontinue the exposure over the splenic area until the erythema had disappeared and the epiphyses only were exposed. In a few days some small dry blisters appeared in the erythematous area and the patch rapidly desquamated, leaving a clean white healthy epidermis. This was the only untoward effect of the x ray treatment and in itself was quite insignificant. It cannot be too strongly insisted, however, that great caution is necessary in exposing to the rays an enlarged spleen in such close proximity to the exterior. Were a burn to intervene the consequences might be disastrous.

During the treatment, careful blood examinations were made either daily or on alternate days and generally immediately after the exposure to the x rays. The accompanying three curves (see chart), indicating the course taken by the white cells, the red cells, and the "polymorphonuclear-myelocyte" ratio, require some explanation. Along the abscissa line are noted the dates on which blood examinations were made. The curves from November to April are composite

the counts

months. T

results of

of the x r

great impo

and the influence exerted on this ratio by the x ray applications have led us to represent this quotient graphically:—

Leucocyte curve (commencing L.) ....
Erythrocyte ,, (,, R.) ▬▬▬
Polynuclear : myelocyte } ,, (,, P/M) ———

In making the differential counts of the leucocytes the following classification was adopted:—

S.L. = Small lymphocytes (percentage).
L.L. = Large ,, ,,
L.H. = ,, hyaline leucocytes (percentage).
N.M. = Neutrophile myelocytes ,,
C.E.M. = Coarsely granular eosinophile myelocytes (percentage).
F.E.M. = Finely ,, ,, ,, ,,
P. = Polymorphonuclears (percentage).
O.E. = Ordinary eosinophiles ,,
Masts = Mast cells
N.R. = Nucleated red cells per 100 white cells.
T. = Transitional forms. These cells were mononuclear and contained large irregular burnt-sienna coloured

As so many observers have noted, a classification of the leucocytes in leukæmia depends largely on the personal equation. Probably no two observers, however conversant with the extraordinary variety of leucocytes in leukæmia, will adopt exactly the same system of classification. The classification adopted above suited extremely well and the same stains were, as a rule, employed on every occasion. These were eosin and methylene-blue, employed separately after heat fixation. Jenner's and Leishman's stains were also employed on several occasions. The following are the results of the different blood counts:—

May 17th (date of commencement of x ray treatment).

The ratio of white to red cells was 1 to 131.

A consideration of the curves will show that the leucocyte count came gradually down from 222,000 per cubic millimetre on the first day of treatment to 23,000 on July 5th—i.e., in the space of six weeks. After this date till the middle of August, when the x ray treatment was discontinued to permit of the patient's going to the convalescent home, the leucocyte count oscillated round a mean of 30,000. On one occasion it dropped to 17,800 but never lower. Thus the reaction to the x rays in our case differed somewhat from that in Bryant and Crane's first case and in Senn's case, in which the leucocytes dropped to normal. From August 17th onwards the leucocytes showed a slight tendency to increase and it was determined to renew the x ray treatment on the boy's return to hospital. The red blood cells during the period of treatment showed the same extraordinary variations which were noted before the commencement of treatment, but the average was much higher. During June, July, and August the mean was about 4,500,000 per cubic millimetre and on several occasions counts of over 5,000,000 were recorded. The hæmoglobin appeared to remain fairly stationary at from 55 to 60 per cent. Regarding the differential counts it will be seen from the curves and the detailed records that as the total of leucocytes diminished the myelocytes, which had previously been the predominating cells, now began to take the second place, the polymorphonuclears taking first place, and the ratio of polynuclears to myelocytes rose from 0·5 before the x ray treatment to 2. The myelocytes, however, showed no tendency to disappear altogether and the blood did not return to normal proportions, as was noted in Senn's and Bryant and Crane's cases.

The effect of the x rays on the blood in leukæmia is, however, exceedingly interesting. In fact, the x rays appear to act exactly as an intercurrent affection does on the leukæmic blood picture. A very systematic description is given of the influence of complicating diseases on leukæmia by Dock.[1] Thus in a case of leukæmia in which influenza intervened the white cells came down from 367,070 to 7500 per cubic millimetre, the myelocytes from 48 to 11 per cent., while the polynuclears rose from 41 to 60 per cent. Dock also notes in several cases a rise in the red cells simultaneously with a fall in the white. In our case this fact was specially noticeable. Further, the counts of nucleated red cells deserve mention. Dock observed that during the low leucocyte stage following an intercurrent affection the nucleated red cells rose to a high level. Our tables for the month of June show that these cells likewise increased largely as the leucocytes fell. During July and August, however, the percentage dropped to a lower level, while the leucocytes remained more or less stationary. During the rapid fall of leucocytes from the middle of May to the middle of June the percentage of mast cells rose to the high level of 16. After this they slowly declined to an average percentage of 3. The lymphocytes did not show any great variation in the total percentage of the three varieties, remaining about an average of 18.

In regard to these interesting blood changes, however, it must never be lost sight of that arsenical treatment may produce similar changes. Thus an extraordinary case was recorded by Simon and Campbell.[2] The patient was a woman, aged 35 years, with enlarged spleen and typical leukæmic blood picture. With large doses of Fowler's solution the leucocytes dropped from 350,000 to 4000 per cubic millimetre in May, 1903. Since that time they have remained within normal limits. The spleen has also diminished, so as now to be barely palpable. Simon and Campbell say that it is the only case on record in which both the splenomegaly and the myelæmia have disappeared and improvement persisted uninterruptedly for a year. In discussing this case Osler remarked that he had three cases in which the leucocytes disappeared entirely in leukæmia. In two of his cases the splenic tumour did not disappear but remained large, while the leucocytes fell to normal. He attributes these effects to long-continued treatment with arsenic in full doses.

We have noted the changes in the myelæmic blood picture produced by the x rays. It remains for us to describe the most remarkable effects the treatment has had on the general condition of the patient and on the splenic tumour. Previously to this treatment the patient was more or less bedridden, owing to the invariable rises of temperature that the mere getting out of bed and lying on a couch produced. Further, walking was always difficult and breathlessness with face-flushings exceedingly troublesome. However, within a month after the commencement of treatment the patient felt distinctly better and was able to walk down to the Roentgen ray room and after exposure to climb the stairs leading to the ward. In fact, the boy walked with the greatest ease and without any bad effect or even rise of temperature.

The following were the abdominal measurements at the commencement of the x ray treatment. Maximum girth (at a level four inches above the umbilicus) was 32⅛ inches, the girth at the level of the great notch (two inches above the umbilicus) was 32 inches, and the girth at the umbilicus was 29½ inches. At the level of the umbilicus the spleen extended two and three-quarter inches to the right of the middle line. At the level of the lower pole of the spleen in the right iliac fossa it extended four and three-quarter inches to the right of the middle line. On May 24th the girths at the same levels were respectively 32, 31, and 28 inches. On August 1st they were respectively 29¾, 29, and 27½ inches. On Sept. 24th they were respectively 30, 26½, and 26 inches. From the middle of August to Nov. 1st the patient remained in the convalescent home and no x ray applications were made. During this period several blood examinations were recorded, for which we are indebted to Mr. James Adams. These showed a slight tendency to increase on the part of the leucocytes, the average being about 45,000 per cubic millimetre, the red cells, also sensibly diminished, averaging 3,600,000 per cubic millimetre. The ratio of polynuclears to myelocytes, however, remained high, with an average of 1·3. During his stay in the convalescent home the patient enjoyed excellent health and on his return to hospital on Nov. 1st his general condition was exceedingly satisfactory. Regarding the patient's weight at different periods it may be noted that on May 9th the weight recorded was 4 stones 6 pounds; on June 6th it was 4 stones 6 pounds 12 ounces; on July 18th 4 stones six pounds six ounces; on August 15th 4 stones 6 pounds; on Nov. 2nd 4 stones 13 pounds 5 ounces; and on Nov. 21st 5 stones 1 pound 8 ounces. The abdominal girths taken at the above levels on Nov. 23rd were respectively 31¼, 30, and 29 inches. It will thus be seen that the effect of the x rays on the splenic volume has been on the whole slight. Very shortly after the commencement of the x ray treatment, however, it was noted that the splenic tumour was markedly softer on palpation and at the present moment it is undoubtedly smaller than it was when the patient left hospital, in spite of the fact that the abdominal girths show only a slight reduction. Possibly the fibrosis which we know to occur in the late stages of the leukæmic spleen will not permit of any great diminution in the splenic volume in our case.

The results of the x ray treatment in the case of our patient have been indeed surprising and it is interesting to compare them with those recorded during the past few months by German, French, and American observers. We have already referred to Senn's and Bryant and Crane's papers on the subject at the commencement of this article, as it was the results gained by these workers which instigated the adoption of x ray treatment in our case. It appears that Pusey[3] was the first to adopt the treatment of leukæmia by the x rays. In one case of the splenomyelogenous type he observed no effect, but in one of lymphatic leukæmia there was a very marked diminution in the glandular and splenic tumour with no noticeable fall in the leucocytes. Recurrence unfortunately took place and finally death ensued. Grad[4] reports improvements in a case diagnosed as leukæmia by x ray treatment. This case, however, loses much of its value from the fact that no results of blood examinations are given. Brown[5] gives notes of a case of myelogenous leukæmia symptomatically cured by the x rays. At the commencement of treatment the red cells numbered 2,600,000 per cubic millimetre, white 800,000 per cubic millimetre, polynuclears 40 per cent., myelocytes 40 per cent., eosinophiles 8 per cent., and hæmoglobin 65 per cent. During the first two months iron and arsenic were also administered. These were then discontinued and the x rays alone were employed. After seven and a half months' treatment the leucocytes had fallen to 7894 per cubic millimetre and the red cells had risen to 4 690 000 per cubic millimetre while the hæmoglobin was 95 per cent The polynuclears were now at a percentage of 74 *and the myelocytes had fallen to 20 per cent* A slight dermatitis appeared once or twice over the exposed splenic area but no bad results ensued Grosh and Stone[6] report a case of leukæmia on which the x rays were tried after a nine months course of arsenic and mercury *The patient a male aged 44 years was admitted in June,* 1903 The blood count gave the following result red cells 2,100 000 per cubic millimetre white cells 960 000 per cubic millimetre, myelocytes numerous Very detailed accounts are given of the blood picture during these nine months It appeared that the myelocytes increased as the disease became more chronic Treatment by the x rays was begun on Feb 24th, but a mixture containing iron arsenic and mercury was continued After 20 sittings the leucocytes had fallen from 252 000 to 10 600 per cubic millimetre and the myelocytes from 52 per cent to 2 per cent The spleen was smaller and the general condition was fair Owing to the development of some superficial burns on the abdomen and the elbow the x ray treatment was discontinued on March 20th Unfortunately however although as Grosh and Stone remark, the burns were healing nicely the patient began suddenly to fail in strength and died from general asthenia At the necropsy the spleen was found to be in a condition of chronic hyperplasia with fibrosis and in the authors opinion x ray treatment could have had little effect on a spleen in this late stage

Krone[7] records a case of splenic leukæmia which he treated with the x rays The patient was an adult male At the commencement of treatment the ratio of white cells to red cells was 1 to 8 This fell after a short time to 1 to 20 and the spleen became softer and smaller The girth also diminished though the body weight rose slightly There was great improvement in the general condition but naturally the patient could not be regarded as cured

Ahrens[8] records a very interesting case in which the ratio of white to red cells was 1 to 1 and the splenic tumour was twice the size of a man s head The patient was a male aged 27 years After 20 sittings there resulted a great improvement in the general condition of the patient who was now able to take long walks After 35 sittings the spleen was just felt below the left rib margin and after the fiftieth sitting it was scarcely palpable The ratio of white to red cells had also fallen to 1 to 525 The case was thus apparently cured and the patient was advised to lead a quiet life and to report himself at intervals A count made at the end of one month showed no notable changes but a few weeks afterwards a remarkable relapse occurred the patient having indiscreetly over exerted himself and thereby caught a chill The spleen was now found to extend again to the ileo cæcal region and the leucocytes had *increased* 20 fold The x rays were again applied and the spleen became a little smaller but the blood was not markedly influenced High fever and sweating intervened ending in death A necropsy revealed a splenic tumour weighing six and a half pounds (German weight) with numerous infarcts In discussing the case Ahrens believes that during the treatment the x rays had rendered innocuous the exciting pathological factor and that on the cessation of the treatment it had once more gained entrance from the exterior or revived in the interior of the body organism producing similar anatomical and functional changes

Aubertin and Beaujard[9] record in one case of myelogenous leukæmia in a male patient 60 years of age with enlargement of the spleen and the liver a considerable rise in the leucocyte count after each application of the x rays It remained high for 24 hours and then fell below the original level The red cells showed no diminution and occasionally there was an increase immediately after the sitting The diminution in the size of the spleen and the liver was trifling but the general condition of the patient was much improved

Gulloz and Spillmann[10] record a case of splenic leukæmia in a woman aged 27 years The splenic area alone was exposed Examination of the blood on Dec 1st before the application of the x rays gave the following result red cells 2 724 000 per cubic millimetre, and white cells 11 200 per cubic millimetre (no differential count was recorded) After four sittings on Dec 1st 4th 8th and 14th the red cells numbered 1 074 000 and the white 8400 per cubic millimetre Further counts made at irregular intervals after each series of x ray *séances* showed invariably a fall in the leucocytes with a slight reduction also of the red cells Once however, the red cells were observed to rise, while the white cells sank On May 10th the red cells were 1 560 000 and the white 4400 per cubic millimetre Gulloz and Spillmann *remark that the leucocytic formulæ were also modified* but unfortunately they do not record any differential counts At the same time the splenic tumour diminished in size and the general condition of the patient was much improved, in fact there was a ' veritable transformation '

Capps and Smith[11] contribute a preliminary report on x ray therapy in leukæmia In ten collected cases of the spleno myelogenous type the splenic tumour decreased in size and in three of these it became barely palpable In four the leucocyte count fell under 10 000 per cubic millimetre with entire disappearance of myelocytes In six lymphatic cases death resulted in four but three of these fatal cases ran an acute or subacute course The fourth showed a great shrinkage of the gland tumours and an improvement in the blood before death took place The remaining two cases show steady continuous improvement in the blood the glands and the spleen Capps and Smith also cite cases by Weber[12] Dunn[13] and Chester[14] but we have been unable to refer to the original articles

Rothe[15] employed the x rays in a case of myelogenous leukæmia in a woman 34 years of age The originally enormous splenic tumour rapidly diminished and the leukæmic blood picture disappeared

Friedl[16] reports two cases of leukæmia in which improvement resulted but is unable to say whether the improvement will be permanent The first case was that of a male aged 59 years Examination of the blood showed red cells 2 525 000 per cubic millimetre white cells 89 335 per cubic millimetre ratio of white to red cells 1 to 28 (myelocytes 38 214 polynuclears 52 143 lymphocytes, 8214) and hæmoglobin 60 per cent After 26 days the spleen was much reduced in size and a blood examination showed hæmoglobin 74 per cent red cells 3 925 000 per cubic millimetre, and white cells 6785 per cubic millimetre (myelocytes 2500 and polynuclears 4285) Great improvement resulted in the general condition The second case was that of a female aged 46 years Examination of the blood showed hæmoglobin 60 per cent , red cells 3 075 000 per cubic millimetre, and white cells 185 000 per cubic millimetre In two days the leucocytes fell to 132 000 (myelocytes 27 857 polynuclears 72 857 and lymphocytes 32 142) In 22 days the leucocytes fell to 50 500 and in 27 days to 31 400 per cubic millimetre The red cells during the x ray treatment rose to 3 375 000 per cubic millimetre The abdominal girth diminished from 92 to 88 centimetres The patient is to be treated further

Schweinburg[17] recorded at the Versammlung Deutscher Naturforscher und Aerzte zu Breslau a case of splenic leukæmia in which treatment by the x rays produced diminution in the size of the spleen and in the number of the leucocytes In the discussion Soetbeer likewise mentioned a case successfully treated by the x rays Krause at the same meeting recorded two cases of pseudo leukæmia *and three cases of leukæmia treated by the x rays* The two cases of pseudo leukæmia showed improvement in the general condition and the gland tumour diminished slightly in one and the splenic tumour in the other Of the leukæmias one was much improved The leucocytes sank from 320 000 to 75 000 per cubic millimetre while the splenic tumour diminished by one third In the second case the leucocytes fell from 156 000 to 24 000 per cubic millimetre, the general condition was improved but diminution of the splenic tumour was not made out In the third case the leucocytes fell from 220 000 to 80 000 per cubic millimetre but the splenic tumour had not as yet sensibly decreased

A very interesting and detailed account is given by Schenck[18] of the results of x ray treatment of a case of lymphatic leukæmia The case was treated in the German Hospital in London Briefly the notes are these The patient a female aged 53 years was admitted on

[11] [illegible] Sept 24th 1904

[15] [illegible] 9th 1904

[16] [illegible] 4th 1904

August 10th. The splenic tumour was fairly hard, reaching to the middle line of the abdomen, two fingers' breadth below the umbilicus. The red cells numbered 1,500,000 and the white cells 45,000 per cubic millimetre. The small lymphocytes formed the great majority of the leucocytes. The hæmoglobin was 30 per cent. The ratio of white to red cells was 1 to 33. From August 25th to Oct. 15th 35 x ray applications were made over the region of the spleen and the sternum. A few days before the commencement of this treatment the general condition of the patient showed a marked improvement which continued for some time during the x ray applications. Then a relapse occurred, accompanied by vomiting, diarrhœa, and albuminuria, which the continued applications of the x rays failed to check, and death occurred on Oct. 19th. The effects on the splenic tumour and the blood picture deserve mention. The spleen became at first somewhat softer but after the thirty-fifth sitting its volume had diminished so considerably that its anterior border was now removed a hand's-breadth from the middle line. Under the x ray treatment the red corpuscles rapidly and progressively diminished while the white cells, which had risen rapidly from 45,000 to 140,000 per cubic millimetre before commencement of the treatment, fell thereafter more slowly to 32,000. There was no apparent change in the differential count. Before the x ray treatment the lymphocytes formed 90 per cent. while the polynuclears formed 10 per cent. of the leucocytes. After 20 sittings these proportions remained the same.

In the same number of the *Münchener Medicinische Wochenschrift* a case of leukæmia treated with the x rays is reported by Cahen. After a few applications the splenic tumour became markedly softer and smaller. Ultimately after 22 sittings the spleen had diminished in volume so much as to be no longer palpable. Further, the white cells fell from 98,560 to 4375 per cubic millimetre, while the red cells rose from 3,925,000 to 4,625,000. The improvement in the general condition of the patient was also remarkable and Cahen hopes to avoid the unfortunate experience of Ahrens[19] by keeping the patient under close observation and applying the x rays periodically from the prophylactic point of view. After the twenty-fifth sitting a slight erythema was observed on the left side, but with ordinary treatment it disappeared.

Joachim and Kurpjuweit[20] report two cases of leukæmia treated by the x rays. The first was a typical case of myelæmia. The patient, a female, aged 39 years, was admitted on May 31st, 1904. She had an enormous splenic tumour. A blood examination on June 15th, two days before the commencement of the x ray treatment, showed hæmoglobin, 40 per cent.; red cells, 2,500,000 per cubic millimetre; and white cells, 693,000 per cubic millimetre; polynuclear cells, 32·8 per cent.; large and small lymphocytes, 2·6 per cent.; mononuclears, 1·2 per cent.; mast cells, 4·2 per cent.; eosinophiles, 1·8 per cent.; eosinophile myelocytes, 1·8 per cent.; and neutrophile ditto, 55·6 per cent. On Sept. 21st the white cells had fallen to 6300 and the red cells had risen to 3,400,000 per cubic millimetre, while the myelocyte percentage fell to 3·5 and the polynuclear percentage rose to 71·5. The last recorded count on Oct. 26th showed that the white cells had risen slightly to 26,000. It is noted that while the leucocytes were diminishing rapidly the mast cells also fell from a percentage of 4·6 to one of 1·4. The lymphocytes also fell at first parallel to the fall in the total leucocytes but later much more slowly. Before treatment the percentage was 6·1; in the first period of x ray treatment it fell to 5, then gradually rose to 13·5. The red cells almost doubled their number during the treatment and nucleated red cells fell considerably. The diminution in the size of the splenic tumour was very marked and the patient's general health had greatly improved. She appeared, in fact, perfectly healthy. The second case was one of chronic lymphæmia. The patient, a male, aged 50 years, was admitted on June 3rd. There was great enlargement of the spleen, the liver, and the lymph glands. Examination of the blood gave the following result: hæmoglobin, 55 per cent.; red cells, 3,200,000 per cubic millimetre; white cells, 385,000 per cubic millimetre; small lymphocytes, 80 per cent.; large ditto, 19 per cent.; and polynuclears, 1 per cent. Soon after admission the patient left the clinic but returned on August 1st, when it was found that the white cells numbered 500,000 and the red cells 2,500,000 per cubic millimetre. Four weeks after the commencement of the x ray treatment the white cells had fallen to 30,000 per cubic millimetre but there was no appreciable change in the differential count. The gland swellings diminished rapidly within the first 14 days and the splenic tumour was also very noticeably reduced in size. An improvement in the general condition was, however, not realised and the red cells sank still lower. The patient left the clinic again on Sept. 5th on domestic business, promising to return in a few days, but he remained away for two months. His condition on return was as follows. He appeared somewhat more reduced than before; the lymph glands showed no change and the spleen had not become larger. Examination of the blood showed: hæmoglobin, 35 per cent.; red cells, 1,600,000 per cubic millimetre; white cells, 8800 per cubic millimetre; small lymphocytes, 45·5 per cent.; large ditto, 30·5 per cent.; mononuclears, 2·5 per cent.; polynuclears, 20·5 per cent.; and eosinophiles, 1·0 per cent. There was thus a considerable rise in the percentage of polynuclear elements. In other respects the blood condition was not satisfactory as the red cells remained at a low level and exhibited the changes associated with severe anæmias.

At a sitting of the Berlin Medical Society on Nov. 23rd, 1904, Grawitz[21] reported shortly on a case of leukæmia treated by him. The patient was a male, aged 54 years. The red cells were 1,000,000 per cubic millimetre and there were 1,250,000 "lymphoidzellen" per cubic millimetre. The spleen, the liver, and the glands were much enlarged. After 23 sittings there was marked improvement. The spleen, the liver, and the glands had been reduced in size and the "lymphoidzellen" had almost completely disappeared. At the same meeting Levy-Dorn showed a case of pseudo-leukæmia successfully treated by radiotherapy. He found that only those gland swellings exposed to the rays disappeared while the others either remained unaltered or increased in size.

It will be seen from a careful analysis of the recorded cases that with one or two exceptions (the cases of Ahrens and Stone) all the patients suffering from myelogenous leukæmia have experienced under x ray treatment remarkable improvement both in the objective and subjective symptoms. At this stage, however, it would be quite premature to presume that the improvement will be a permanent one. Nearly all the observers have been so surprised at the almost immediate effect of x ray treatment on the blood, splenic tumour, and general condition of the patient that they have published their results forthwith. When these so-called "cured" cases and those in which marked improvement has resulted have been under observation for some considerable time, with or without renewal of the treatment, we shall be in a better position to judge of the true value of this novel therapeutic method. Thus Senn, in a letter (March 20th, 1904) to Grosch and Stone,[22] reported that his two cases of pseudo-leukæmia were well and the case of myelogenous leukæmia which made such an excellent recovery had returned with a moderate relapse and was again under x ray treatment. At present, however, we can have no doubts regarding the more or less rapid effects of x ray treatment on the blood picture, the splenic tumour, and the general condition. In some cases (notably Senn's and Bryant and Crane's first case) the leukæmic blood picture is said to have entirely disappeared, while most of the observers, including ourselves, have been enabled to record only a rapid fall of the white cells to a normal, or approximately normal, level, this fall being invariably accompanied by a great diminution in the myelocyte percentage and a corresponding rise in the polynuclear percentage. In other words, the essentially leukæmic character of the blood has shown a tendency to disappear but not entirely. Detailed blood counts have, however, been recorded in only a few cases. A very satisfactory feature has been the almost invariable rise of the red cells to a higher level, while the leucocytes fell. This feature was notably absent in the cases of lymphatic leukæmia where, it must be confessed, the general results of the x ray treatment have been only fairly satisfactory. Undoubtedly in this disease also the lymphocytes are very markedly reduced under the influence of the x rays, though there does not invariably occur that modification in the leucocytic formula which is so marked a feature in the myelogenous cases. The splenic and glandular swellings of lymphatic leukæmia and of pseudo-leukæmia

[22] Loc. cit.

(Hodgkin's disease) are also susceptible to x ray treatment. It is curious that the general condition does not appear to improve so noticeably in lymphæmia as in myelæmia. Possibly, as Capps and Smith[23] also remark, many of the cases of lymphæmia treated with the x rays have been running an acute or subacute course and are therefore not so readily influenced by radiotherapy. Capps and Smith also state that the chronic form of lymphatic leukæmia responds to the x rays even more promptly than the spleno-myelogenous type. The effects produced by radiotherapy on the splenic tumour in myelæmia have been variable. Senn, Bryant and Crane, and Ahrens reported an almost complete disappearance of the splenic tumour, while others have been content to record only a moderate reduction in volume. In a few cases the only change was one of consistence, the tumour becoming much softer and more easily palpated. It must be remembered, however, that a slight reduction of volume in such an enormous splenic tumour as that found in leucocythæmia is rather difficult to certify clinically and there is little doubt that the ultimate result of x ray treatment on the splenic tumour will depend largely on its histological features initially.

When fibrosis has occurred in the later stages of the leukæmic spleen it is doubtful in the light of Heinecke's results whether much reduction in volume can be expected. However, we shall have to await the results of further work before we can express any dogmatic opinions on this point. In nearly all the cases, except those of lymphatic leukæmia, there was a very marked improvement in the general condition and wellbeing of the patient and this is perhaps the most satisfactory element in the treatment by radiotherapy, for leukæmia has almost invariably progressed towards a fatal conclusion.

It behoves us finally to discuss as briefly as possible the *theories which have been put forward to explain the mode* of action of radiotherapy in leukæmia. Naturally this subject is as yet in the early experimental stage, but already one or two important contributions have been made towards the elucidation of x ray influence on the blood-forming organs. Senn believed that his results in leukæmia were due to an antiparasitic action on the part of the x rays and to those who sympathise with Löwit's views on the etiology of leukæmia this explanation of Senn may appear fairly plausible. To Heinecke's work[24] we have already referred. His results appear at least to afford a physiological foundation for radiotherapy in leukæmia, in so far as the excess of white cells in the circulating blood and the presence of abnormal cell elements are concerned. But this is, after all, only a symptom. Whether the x rays directly influence the exciting factor in leukæmia is another question. Further, the bone marrow is probably the tissue whose function is primarily at fault and Heinecke's remarks on the effect of the x rays on the bone marrow have been called in question lately by Mosse and Milchner[25] as being too vague. These latter observers working with rabbits have found alterations in the lymphoid and myeloid elements of the marrow under the influence of the x rays. These changes consisted in a partial destruction of the white cells of the marrow, while the protoplasm of the neutrophile cells especially showed a great deficiency of granules. Curiously enough, the red cells, nucleated and non-nucleated, were not affected. The authors argue from these facts that there is a field for radiotherapy in leukæmia but not in pernicious anæmia. These facts are interesting in the light of the results of x ray therapy on the red cells in the cases of spleno-myelogenous leukæmia. It was found that the red cells invariably rose to a higher level as the leucocytes fell. We must remember, however, that remarkable variations may occur in the red counts from day to day in cases of leukæmia which are not under any special treatment. We were particularly struck with this fact in our case during the months preceding the adoption of x ray treatment.

[illegible][26] and Mosse and Milchner[27] [illegible] leukæmic blood and normal blood corpuscles *in salt solution to the direct action of the* x rays but no changes of any kind were noted either in the leukæmia blood elements or in the normal red blood corpuscles. These experimental results would seem to point to the necessity of subjecting all the bone marrow in the body to the influence of the x rays—i.e., on the supposition that leukæmia is primarily a bone marrow disease. Failure to do so may have been the cause of the generally *incomplete response of the myelæmia* to the x rays, for, as noted above, the leucocytes sank under the influence of the x rays to a very low level, while the myelæmic picture, though much modified, still remained; and further, on the cessation of x ray treatment after this low leucocytic level had been reached, there was a tendency on the part of the leucocytes to rise slightly. This was noticeable in our case. After the leucocytes came down to a level of 20,000 per cubic millimetre in our patient no amount of exposures of spleen and epiphyses to the x rays would produce a further reduction.

It has been shown by Lépine and Boulad[28] that enzymes can be influenced by the Roentgen rays and in the light of Ehrlich's view that in myelæmia there exists a chemiotactic enzyme in the blood it is possible that the destruction of this enzyme prevents the further inroad of leucocytes into the circulating stream. However, as Joachim and Kurpjuweit maintain, the x rays in leukæmia do not act directly on the blood but on the diseased leukæmic tissue. These observers in a fresh case of leukæmia exposed only the liver area to the rays but there was no result after 14 successive daily séances. It was also shown that exposure of the spleen only produced a great fall in the leucocytes in the first case described by them, while later exposure of the bones only was also successful. The authors intend in their next case of leukæmia to begin by exposing the bones only to the x rays. In fact, it is possible that the comparative effects of radiotherapy on the bone marrow and the spleen may add much to our knowledge of the pathology of leukæmia.

We may refer to one other possible explanation of the action of the x rays. It has been shown by Schwarz[29] that radium rays have a destructive action on the lecithin of the hen's egg and as lecithin is an invariable constituent of cells *undergoing rapid development as leucocytes, spermatozoa,* and tumour elements, the reduction in leucocytes in leukæmia by the x rays may be due to a similar cause. The presence of lecithin bears so important a relationship to the developmental capacity of the cell (Hoppe-Seyler) that its disintegration would be fatal to further cell-development.

Wohlgemuth[30] does not find that radium has a selective action on lecithin. He thinks rather that the breaking-up of the lecithin in egg albumin is due solely to the influence of autolytic ferments contained in the egg. The action of these rays on living tissues and cells opens up a very wide field for research, for as yet the science of experimental cytology is in its infancy.

In conclusion, we may note that on Dec. 1st x ray séances were resumed in our case. Any further developments which may arise in our patient we hope to communicate at a later date.

THE INFLUENCE OF RAINY WINDS ON PHTHISIS.

By WILLIAM GORDON, M.A., M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE DEVON AND EXETER HOSPITAL, ETC.

(Concluded from p. 15.)

PART II.—WIND AND RAIN IN THE MOST SUCCESSFUL PHTHISIS HEALTH RESORTS.

IT is impossible to make any general statement with regard to the effects of strong rainy winds on phthisical patients in foreign countries because sufficient material does not exist; I will only refer to a statement sent me by Dr. A. A. Rodriguez who has been so good as to make a collective inquiry amongst the medical men in the Azores. It will serve as an example of existing difference of opinion. (*a*) Some have discovered no effect of any wind on phthisis patients. (*b*) Some *have noticed an injurious effect of the* warm damp winds from the south. (*c*) Some have noticed an injurious effect of these winds from the south and a beneficial effect of the winds from the north which are dry. But there remains the indirect evidence of the relations of health resorts to strong rainy winds. At present it would be scarcely justifiable to impugn the resorts which are exposed to such winds, but it will be useful to inquire whether any admittedly very successful health resorts are exposed to them. Davos in winter is singularly calm. Nordrach is exceptionally well sheltered. Görbersdorf is well sheltered from rainy wind. Weissenburg lies in a deep gorge almost windless. Eaux Bonnes and Cauterets are in deep sheltered valleys. Jauja and the other resorts of the Peruvian Andes lie in deep well-sheltered valleys. The health resorts of Argentina are sheltered from rainy winds. The Khirghiz Steppes are very free from rain. Colorado and New Mexico have much wind but it is usually dry. The Darling Downs of Queensland have little rainy wind. The Karoo, Orange Free State, and Transvaal have no frequent rainy winds. One common characteristic, therefore, of these climates, otherwise so dissimilar, is their freedom from prevalent strong rainy winds.

It may be objected that most of the resorts mentioned are at so-called high altitudes and, indeed, the efficacy of the majority of them is generally attributed to their height above sea-level. So a few words must be said on this point. Apart from other considerations, to be presently mentioned, it seems to me that in view of the failure of the existing Indian hill stations as phthisis health resorts the effect of altitude on phthisis patients must be at least subordinate to the effect of the rainy winds to which Indian hill stations are mostly exposed. Their unsuitability for phthisis has scarcely received the attention which the great experience and ability of those who have condemned them should have insured. Sir Joseph Fayrer refers to them as follows.[1] Simla, 6953 feet high, "should be avoided by the phthisical." Ranikhet, 6068 feet high, is not of much real service. Darjeeling, 6912 feet high, more useful in pulmonary organic disease than the foregoing, enjoys considerable immunity from wind and storms. Pachmari, 3564 feet high, is ineligible as a resort for phthisis. Mount Aboo, 3945 feet high: phthisis is not benefited there. Mahabaleshwar, from 4500 to 4700 feet high, after the mists set in in May is prejudicial to phthisis. Nilgherries, average elevation of stations about 6500 feet, are not advantageous in phthisis. Newera Eliya (Ceylon), 6150 feet high, "has an evil reputation for cases of phthisis." At Dalhousie, 6800 feet high, in 1897, Surgeon-General Keogh informs me, there were six admissions for phthisis in the first stage of the disease. These were "returned to the plains, as the climate was too severe for them."[2] I shall refer again to high altitudes in considering their influence on phthisis prevalence.

The freedom from strong rainy winds, therefore, which characterises the very successful resorts, fits in with the observation made in Devonshire, that such winds are injurious to phthisis patients.

PART III.—OTHER INFLUENCES.

Lastly, it is necessary, in order to establish the validity of conclusions based on the facts so far enumerated, to consider the relative strength of the other influences known or supposed to affect phthisis. These other influences may be thus enumerated:—

Climatic influences.—(1) Soil; (2) altitude; (3) temperature; (4) dry wind, especially when dusty; and (5) rainfall.

Social influences.—(6) Density of population; (7) insanitation; (8) poverty; (9) occupation; (10) race; and (11) preventive measures.

Pathological influences.—(12) Prevalence of other forms of tubercle; (13) prevalence of other "respiratory diseases"; and (14) prevalence of malaria.

Soil.—Current opinion on the relation of soil to phthisis rests on Sir George Buchanan's work in 1851 to 1860.[3] If his figures be examined, it will be found that *rainy wind had a greater influence than soil*, although the area used was well adapted to show the effect of soil and ill adapted to show the influence of rainy wind. The south-west in that area is the prevalent wind,[4] and as elsewhere in the south of England it is a rainy wind. If Buchanan's districts are arranged in his own order of ascending phthisis death-rate (see Table XV.) it will be found that the districts obviously sheltered from south-west wind come at the beginning of the table and those obviously exposed at the

Here the differences in the death rate are much more obvious and uniform and the average of the exposed districts is 49 per cent of itself higher than that of the sheltered

two chief exceptions on which he lays such stress,[5] —viz, Sheppey and Thanet—the low death rate of Sheppey can be fully explained by its shelter from south west wind, an

rate of Romney Marsh can be
at least
For the south-
west win
lined by several
ridges of
inches whilst

Romney Marsh flat and largely below high tide level, walled round with sand dunes and dykes and with a low rainfall about 16 inches at Dungeness, cannot be said to be exposed to rainy winds It is curious that Buchanan s other doubtful districts should have death rates corresponding in the main with their south westerly shelter or exposure where these can be fairly stated

Altitude —The idea that phthisis death rate lessens as altitude increases originated in the observation of its rarity at certain places in the Andes at heights of from 5000 to 13 000 feet Attempts have been made to prove this effect of altitude, but the results have been disappointing Merbach s table for Saxony (see Table XIX),[6] if the towns under 200 metres high be excluded as probably the largest and most industrial, merely tends to show that altitude has no effect Corval s table for Baden (see Tables XX and XXI),[7] which includes all forms of tuberculosis as well as

so-called "chronic pneumonia," does seem to show a decrease in the death-rates with increasing height, but this increase is a very irregular one. Müller's table for Switzerland (see Table XXII.)[8] shows a still less regular decrease and when his table for the agricultural cantons with imported cases excluded is examined (see Table XXIII.)[9] no influence whatever of phthisis can be traced between 700 and 1800 metres of altitude. The latest table prepared to show the influence of altitude with which I am acquainted was published in 1895 by the Government of the Grisons. This canton affords an excellent field for comparing death-rates both at different altitudes and under different conditions of wind shelter and exposure.

TABLE XXII.—*Müller s Table for Switzerland published in 1876. The Periods of Observation in Various Cantons vary from 1 to 5 Years.*

The rainy winds of Central Europe are the south-west, west, and north-west, together with, to a less extent, the south-east and south. The west wind can only reach the Grisons much broken and dried; the south-west as a rainy wind only affects considerably the Upper Engadine. The south-east has probably some effect as a rainy wind on the highest villages of the valleys which run down into Italy. Only the north-west, north-north-west, and west-north-west, entering at the gap of the Rhine valley, can widely affect the canton. These north-westerly winds are especially prevalent in the summer months, the time of the principal rainfall of this region.[10] The table for the Grisons was arranged in unequal divisions of altitude and it was first necessary to re-arrange it in divisions of 200 metres-intervals. (See Table XXIV.) So arranged, a definite effect of altitude was by no means clear, and at each height there were pronounced exceptions suggesting some more powerful influence. It seemed possible that this was rainy wind. Accordingly, a table was constructed (see Table XXV.) showing the phthisis death-rates in localities exposed to various winds and it was at once obvious that a higher death-rate accompanied exposure to winds from any westerly quarter. Next, a table was drawn up of localities with death-rates under 5 per 1000, and of localities with death-rates over 10 per 1000. (See Table XXVI.) The places with lower death-rates were

TABLE XXIV.—*Tuberculosis in the Grisons: Being a Summary of Tables published by the Cantonal Government in 1895, rearranged for Equal Intervals of Height.*

Of these Haldenstein may get deflected westerly winds Its inhabitants and those of Sur can scarcely go any distance out of doors without encountering north west wind Fetan lies so high it probably gets some S W down the valley

then with few exceptions seen to be sheltered from all westerly winds whilst the places with the higher death rates were with two exceptions exposed to W, S W or N W winds The winds causing higher death rates were usually north westerly So another table was constructed comparing at each altitude the death rates in the populations sheltered from north west north north west and west north west winds with the death rates in the populations exposed to these winds (See Table XXVII) The result was very striking At each level the exposed population suffered far more (twice to seven times as much) from phthisis than the sheltered population But two other facts became also obvious—namely that as altitude increased a greater proportion of the people tended to live in sheltered places, and that in neither exposed nor sheltered places was there any indication that altitude lessened the mortality Finally, to investigate fairly the question of the effect of altitude a table was made out showing the death rate at successive heights in places sheltered from all rainy winds (Table XXVIII) From this table the conclusion seems inevitable that altitude alone has extremely little if any influence on the death rate from phthisis The supposed influence of altitude would appear in fact to be an indirect influence of rainy wind and of the consequent increasing bleakness at increasing heights which drives the inhabitants to live in sheltered places

TABLE XXVII—*The N W, N N W, and W N W Winds Effects of Exposure to, and Shelter from them at Various Heights (Summary) It should be observed that the exposed populations at 801–1000 at 1001–1200 and at 1401 1600 metres are very small*

Altitude in metres	Fully exposed to N W		Fully sheltered from N W	
	Population	Death rate per 1000	Population	Death rate per 1000
Up to 600	14 039	14 4	4874	5 3

1401 1600	270	18 5	8273	3 8
1601 1880	0	—	4966	8·6

TABLE XXVIII—*Sheltered from all Westerly Winds and from Sirocco (Summary)*

		Population
Up to 600 metres	3 9 per 1000	2898
601 800	4 7	3173
801 1000	4 1	971
1001 , 1200	2 8 ,	4254
1201 1400	2 3 ,	5059
1401 , 1600	4·9	3693
1601 1880	6·7 ,	3538

Now how can this conclusion be reconciled with the claims of absolute or comparative phthisis immunity at certain other high altitudes? If the places in the Andes which have a well grounded reputation are examined it will be found they are protected from the prevalent rainy winds In North America the city of Mexico is very free from strong winds and in the region of the Rockies the winds are usually dry The highlands of Persia and of South Africa are extremely dry the plateau of Abyssinia is ringed in by high mountains The northern spurs of the Carpathians are sheltered from the rainy westerly winds Briançon is shut in from westerly winds Hirsch is wrong about India for in Coorg phthisis is common[11] and amongst native Indian troops it appears to be most frequent at the hill stations[12] The three places in the Himalayan system of mountains where phthisis appears to be rare—viz Kashmir[13] the valley of Nepaul[14] and Manipur[15]—have no strong rainy winds There is in fact no evidence whatever that altitude *per se* has any influence on the prevalence of phthisis

[illegible] seems to have little if [illegible] an [illegible] phthisis may be rare as in [illegible] Greenland[16] and in hot climates rare as in Upper Egypt or prevalent as in Tahiti[17] In climates of small mean annual range of temperature it may be rare as at Lagos or common as at Georgetown in British Guiana, and where the mean annual range is great, rare or absent as in the Khirghiz Steppes or frequent as in Mid Russia Even mean daily range seems to make no marked difference, phthisis is rare at Luxor and common at Moscow, both of which have a great daily range

Dry winds—Dry winds seem to have little effect as compared with rainy winds The plains of Colorado South

SOME CLINICAL OBSERVATIONS WITH NEW REMEDIES.[1]

BY NESTOR TIRARD, M.D. LOND., F.R.C.P. LOND.,
PROFESSOR OF MEDICINE, KING'S COLLEGE, LONDON; PHYSICIAN TO KING'S COLLEGE HOSPITAL, ETC.

WHEN I last had the honour of reading a paper before this society on Some Dangers of Hypnotics certain members were kind enough to express a hope that my next contribution would deal with clinical observations concerning some of the new remedies which had been used in my wards or in my private work. The kindly reception of my last paper has encouraged me to attempt to-day to meet this desire and to place before you some observations which, though perhaps fragmentary and inconclusive, may yet, I hope, prove of interest and at least afford material for discussion and for an interchange of records of experience.

The term "new remedies" I employ to include some preparations which are not to be found in the British Pharmacopœia, some which have been introduced since the issue of the current Pharmacopœia in 1898, some which, for aught I know, may never be admitted or may not appear under their present familiar names if they are protected by patent rights. This is not a question which concerns me greatly, the important point being the investigation of their claim to any consideration. It is impossible to wait for this question to be settled by official authority. Our patients look to us for guidance when perplexed with persistent advertisements and we must be in a position to answer their inquiries without delusive evasions. In dealing with new remedies the rule I have followed, and I believe it is the only safe rule, is not to be led into trying the last new remedy without being in possession of full information of its nature and composition. Details of the method of preparation are not so important, but we must know something about a new drug besides the name and the purposes for which the manufacturer deems it may be of service.

The drugs I propose speaking of to-day are the following: uricedin, urotropin, aspirin, mesotan, and ovoferrin or iron vitellin. You will find that my remarks are not necessarily in praise of any of these preparations; while indicating what I take to be the limits of utility I wish also to point out certain dangers or inconveniences which may arise. I hold no brief on behalf of these drugs but wish to tell a plain unvarnished tale of the results I have had with them and at the same time to give some words of warning against their indiscriminate employment. Each and all of these may give rise to trouble. They might almost be compared to dynamite or gunpowder; they are useful if properly employed, hazardous if used unskilfully and recklessly. When the possibility of danger is realised there is comparative safety, but if used without due knowledge great risks may be incurred. We frequently hear that every man is "a fool or a physician by the time he is forty." This is a hard saying, since we know that all men of forty are not legally qualified to practise. Perhaps there is a fallacy in the major premiss, but, however that may be, you will soon see that I should not recommend the employment of any of these drugs by the unqualified public.

Uricedin.—The first drug on my list is uricedin. According to Martindale's Extra Pharmacopœia this is a German speciality which occurs in brownish-yellow granules which are soluble in water. It is said to be prepared from concentrated lemon-juice by treating it with sulphuric and hydrochloric acids, neutralising with soda, adding lithium citrate, and evaporating to dryness. It has, according to the same authority, been recommended for gout, gravel, urinary calculi, articular rheumatism, and uric acid diathesis, and the dose is given as from one to two drachms. The statements that have been made respecting this drug are rather conflicting. It has been said that it imparts to the urine the property of dissolving uric acid; that it exercises no injurious effect upon the stomach; that large doses have only been known to cause a slight relaxation of the bowels; and that it converts insoluble uric acid into the more soluble acid urate of sodium. My clinical observations agree generally with these statements but I should be disposed to lay greater stress upon the laxative action. Several of my patients with chronic gout have volunteered the remark that in the moderate doses which I have employed they have found that an easy satisfactory action of the bowels has been produced. One patient, who had suffered long from gout, expressed more gratitude for the pleasant laxative action than for any relief of pain. In acute gout, both in hospital practice and in private work, it has not given me the same degree of satisfaction, nor have I been able to confirm the statements relative to its value in cases of renal calculus. I have tried it in some cases of migraine but the results have not been encouraging. To judge from some of the recent literature which has been circulated to the medical profession I fear that, despite its pleasant laxative action in chronic gout, uricedin is likely to suffer in general estimation on account of exaggerated claims for its employment. It does not inspire confidence to find that it is recommended that its use should be "persevered with for a long time—perhaps even for years."

Urotropin is almost too familiar to need formal introduction but for the sake of consistency it may be well to remind you that it rejoices in the somewhat ponderous chemical name of hexamethylenetetramine and that it is prepared by combining ammonia and formaldehyde. Martindale states that it consists of colourless crystals with an alkaline reaction; it is easily soluble in water, less so in alcohol, and almost insoluble in ether. It is further stated to be a valuable diuretic and solvent of uric acid concretions, to relieve cystitis associated with incontinence of urine, and to destroy typhoid bacilli in the urine. There is, however, one word of warning—viz., that it may cause hæmaturia unless well diluted. The dose is given as from five to 15 grains. On looking into the literature connected with urotropin I have been sorry to find that the list of its misdeeds has been considerably increased. It has been held to be responsible [illegible] symptoms: irritation of the [illegible] al pain, a measles-like rash, [illegible] strangury, and irritant action on raw surfaces in the urinary passages and hæmoglobinuria. These actions have been said to be due to special susceptibility to formaldehyde, to interference with the usual disposition of formaldehyde in the body, or to the liberation of an unusually large quantity of it. Some two years before these suggestions were made Cammidge maintained that the liberation of formaldehyde did not occur within the body, that the urine of persons taking 30 grains of urotropin a day did not contain formaldehyde, and he suggested that the antiseptic properties might be due to the formation of new urotropin compounds.

My experience with urotropin in private work has been far greater than in the wards, since many patients for whom the drug might be employed are scarcely sufficiently ill to require ward treatment. At the outset let me say that the long catalogue of ill-effects has not come within my experience; in only one case has there been complaint of slight lumbar pain, and although at the time I did not feel satisfied that it was due to the urotropin it certainly ceased when the drug was discontinued. I am inclined to attribute this freedom from unpleasant symptoms to the fact that I have invariably given instructions that the powder should be taken in at least five ounces of water and have generally employed Contrexéville water for this purpose. The cases in which I have given urotropin have been of varied nature; the general indication has been the presence of pus in the urine, whether resulting from irritation of the renal pelvis by calculi or by crystals of uric acid, or when associated with offensive conditions from the presence of micro-organisms. I would not venture to say that this treatment has sufficed to dissolve uric acid concretions—indeed, in some of my cases subsequent surgical operations were required; but, on the other hand, I would affirm that in every case I have found that the urine speedily lost its offensive character and that there was generally a rapid decrease in the amount of deposit. Further, I can say that those who had hitherto been passing quantities of sand lost this trouble during the treatment; this improvement may, however, have been due to the increased quantity of liquid consumed rather than to a specific action of urotropin. In leaving this drug I would venture to suggest [illegible] arise during its administ[illegible] ain whether it has been [illegible] tions before too hastily [illegible] line of treatment.

[illegible] garded as acetyl salicylic

[1] A paper read before the Therapeutical Society on Dec. 20th, 1904.

useful vision. Of course, in considering this subject such simple cases as those in which the metal is small and is lying in the anterior part of the eye (the anterior chamber, the iris, and the lens) must be excluded. It is probable that of those cases in which the metal has penetrated into the vitreous body and has been extracted by the electro-magnet, the proportion in which the eye thereafter recovers or retains useful vision is very small, probably not 5 per cent. In a paper which I communicated to the Congress of Ophthalmology at Lucerne in 1904 I showed that of 1000 eyes excised in the Glasgow Eye Infirmary 244 were lost in consequence of an injury by a chip of metal. This number is small compared to the total of cases in which the eye was injured to a serious extent but not excised, however, but it is difficult to say at all accurately in what proportion of the latter metal had been extracted by the electro-magnet.

In the great majority of cases in which eyes are excised after injury it is found that inflammation of the ciliary body is the cause of the destruction; in the remainder the eye is lost in consequence of intra-ocular hæmorrhage. Now we may take it as an accepted fact that cyclitis in such cases is due to either infection by micro-organisms conveyed into the eye by the metal or some other means or to the formation of an irritant in the eye as the result of chemical action on the metal. If, then, the irritant is the result of such chemical action, even in a small proportion of the cases, manifestly the sooner the metal is removed the better. It is perfectly true that in certain cases metal has remained in the eye for many years and has done but little damage. This is so, of course, because the foreign body has become encapsuled and the products of chemical action pass not into the vitreous body but into the general circulation. In a vastly larger proportion of cases the presence of a chip of metal does irreparable damage to the eye in which it is lodged. There is, then, a good argument for attempting the extraction of chips of metal if it can be shown that even in a few cases out of every hundred eyes from which metal is extracted the organ preserves useful vision. Three cases in which this has been the result have come under notice and a short account of each is given here.

CASE 1.—A girl, aged 19 years, was seen on Dec. 25th, 1903, as she had received a blow on the right eye from something whilst "pulling a Christmas cracker" the previous evening. There was a large wound at the upper part of the ciliary region of the right eye. It was radially situated, was very ragged, and allowed of prolapse of both iris and ciliary body. As it was suspected from the appearance of the wound that there was a foreign body in the eye the point of a large electro-magnet was brought close to it and at once a large shining body came to the surface and was easily seen through both the pupil and the wound. A small magnet was then used but though the metal rose to it well it could not be induced to come out through the wound owing to its large size. Ultimately, after considerable enlargement of the wound and with the aid of the large magnet again a piece of tin-plate measuring a quarter of an inch square, much curved, and with very ragged edges was removed from the eye. The appearances were so bad that no hopes were entertained of saving the eye, but nevertheless the edges of the wound were carefully trimmed. The eye was dressed "cold" and atropine was used freely. The subsequent history of the case was that of a very successful cataract extraction. The wound healed wonderfully quietly and well, especially considering its situation and the amount of disturbance to which it had to be subjected. There was no iritis, the iris remaining mobile though its torn edge was still adherent to the wound. The lens had been injured and dissolved quietly away, its solution being aided on two occasions by a gentle discission. Now, after nearly a year, the girl can see with suitable glasses absolutely perfectly up to the normal standard, $\frac{6}{6}$, and the very finest print.

There are several points of special interest in connexion with this case, the first being the cause of the injury. When the electro-magnet was tried it was only with faint hope of success as, so far as was known, there should be no metal in the composition of a "cracker." The fact that in some of these objects for the entertainment of children there is metal shows that they are not such safe things to put into the hands of a child as was formerly thought. The position of the metal in a "cracker" is interesting and instructive. The explosive part consists of two strips of paper coated probably with chlorate of potassium and a little sand and it is by drawing the strips quickly past one another that the explosion is caused. Formerly the strips were held in apposition by a binding strip of paper but in the "cracker" which was used in this case the strips were held together by a piece of tin-plate lapped round them in such a manner that the explosion took place in the fold of the tin. In one of the "crackers" fired as an experiment the tin was burst open so violently that a portion of it passed out through the paper wrappings and went eight feet across a room. It may be said here that the name of the maker of the cracker could not be discovered. In another way, however, the case was particularly interesting and important. As the case was regarded as practically hopeless from the first a very grave prognosis was given to the family medical attendant and parents, indeed it was considered probable that the eye would have to be sacrificed in order to save the other. Nothing was left undone, however, to save it and the manner in which the wound healed in spite of adverse circumstances was little short of miraculous. There is now no fear for the eye, which preserves almost the natural appearance as the coloboma is upwards, a fact specially fortunate in the case of a woman.

CASE 2.—The next case is that of a man, aged 40 years, who in August, 1891, got a chip of metal into his right eye whilst working at a vice. He came to the Eye Infirmary at once where it was found that there was a large wound of the eye at the upper part of the cornea with laceration and prolapse of the iris and lens. As it was suspected that there was metal in the eye the point of an electro-magnet was introduced through the wound and pushed down and backwards for three-quarters of an inch. At this distance it was moved about a little and a sharp "click" was heard denoting the presence of a chip of metal of considerable size. When the magnet point was withdrawn the metal was adhering to it. The metal measured a quarter of an inch in its longest and one-eighth of an inch in its shortest diameter. The remains of the lens were drawn off and the edges of the iris were trimmed and replaced with great care. Atropine was freely used and the eye was dressed "cold." After a small operation, with the object of breaking up the capsule of the lens and an iridectomy to make a pupil free from the corneal scar, the eye could see with a suitable glass in January, 1901, nine years after the accident, $\frac{6}{60}$ and "time on a watch."

CASE 3.—A man came to the Eye Infirmary in June, 1904, having received a blow in the right eye whilst at work 24 hours before. There was a small wound in the ciliary region at the nasal side of the cornea but no prolapse of contents. As the wound penetrated the sclera it was thought probable that there would be metal in it and the point of the large magnet was brought close to the eye but no pain was experienced. The point of a small magnet was then introduced through the wound and at a distance from the surface of half an inch a chip of metal was found and extracted. Considerable reaction followed and there was much effusion of both inflammatory material and blood into the eye. After a month, however, the eye became quiet and the tension, which had been below the normal, rose again. Three months after the accident the man could see with this eye nearly $\frac{6}{60}$ and as the blood clot in the eye was absorbing well it is confidently expected that still further improvement will take place.

These three cases, then, show that what may be called useful vision may remain after the extraction of a chip of metal of considerable size from the eye. It is, of course, a matter of the greatest importance that the patient should be seen at as early a date after the injury as possible. The use of the magnet is not difficult to learn, but it requires a little confidence to push the investigation far enough in some cases. The greatest care must be taken that the point of the magnet is sterile, of course, and all other precautions usual in surgery must be carried out with care; and, lastly, every form of treatment which ophthalmic medicine indicates should be used to prevent the occurrence of iritis and cyclitis.

Glasgow.

GLOUCESTER COUNTY ASYLUM.—At a recent meeting of the Gloucester county council it was decided to extend the county asylum at Barnwood by the erection of two blocks for epileptic patients at an estimated cost of £4000. It is proposed to erect one block for female patients shortly; the remaining one, for male cases, is to be built later.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

TWO CASES OF CONGENITAL MORBUS CORDIS WITH ATRESIA OF THE PULMONARY ARTERY AND OTHER DEFECTS

By Sydney W Curl, M A, M B Cantab,
M R C P Lond,
PATHOLOGIST AND BACTERIOLOGIST TO THE NORTH EASTERN HOSPITAL FOR CHILDREN, BETHNAL GREEN N E.

THE following two cases are examples of congenital morbus cordis with atresia of the pulmonary artery and other defects

CASE 1 —The patient, who was a female child, aged three months, suffering from hare lip and cleft palate, was admitted into the North Eastern Hospital for Children for operation The mother had several other children, all of whom were quite well, and there was no history or sign leading to the suspicion of a syphilitic taint The patient, usually of a natural colour, was however, subject to attacks of dyspnœa with cyanosis Clubbing of the fingers or toes was absent and no heart murmur could be detected The child died suddenly before any operation could be undertaken

A post mortem examination r [illegible] the heart The lumen of the [illegible] from the right ventricle and fo [illegible] was completely obliterated, the artery being represented by a firm fibrous cord, beyond this point the lumen became evident and expanded into a rather narrow but otherwise normal pulmonary artery The cavity of the right ventricle was dilated and its walls were hypertrophied The aorta, which was enlarged arose from both ventricles but chiefly from the right The interventricular septum was deficient at its upper part and the auricular septum was also incomplete This specimen was exhibited at a meeting of the Society for the Study of Disease in Children in November, 1904

CASE 2 —The patient was a child, six months old, who had been cyanotic since birth There were three other children in the family, all of whom were healthy and no history of syphilis could be obtained The only abnormal physical sign connected with the heart was a systolic murmur heard all over the præcordium but most distinctly in the position of the apex beat Death took place from bronchitis and œdema of the lungs

The condition of the heart found at the necropsy was as follows There was no direct communication between the cavity of the right ventricle and the lumen of the pulmonary artery, this vessel commenced blindly at the upper part of the anterior wall of the right ventricle, there was no trace of the pulmonic semilunar valves The cavity of the right ventricle was abnormally small and its lowermost part was rounded, the walls were enormously thick (considerably thicker than those of the left ventricle), especially towards the apex of the heart where they measured nearly three quarters of an inch through The right auricle was very much dilated and its walls were somewhat hypertrophied, the foramen ovale was patent, admitting the tip of the index finger The aorta which was larger than usual communicated with the pulmonary artery by means of the patent ductus arteriosus

In the English and continental literature of the last ten years to which I have had access I have found only three cases of complete closure of the pulmonary artery recorded, one of these was reported by Dr R J Probyn Williams[1] and the other two are described by Dr G Carpenter[2] Code[3] reports a case in which the pulmonary artery was absent, its place being taken by a vessel which arose from the concavity of the arch of the aorta and divided into two branches which passed to the lungs

For the clinical abstracts I am indebted to Dr R M Im Thurn and Dr Powell of the North Eastern Hospital for Children and my thanks are due to Dr W A Wills and Mr E C Stabb for permission to publish these cases

Devonshire street W

A CASE OF SUDDEN AND FATAL ILLNESS WITH UNUSUAL SYMPTOMS

By Harold Ward Evans, M R C S Eng, L R C P Lond

THE following case will probably be of interest on account of its sudden onset and extreme severity At about 10 P M on Dec 18th, 1904, I was asked to see a girl, aged 13 years, who was supposed to be in a fit On arriving at the house I found the patient suffering from a most severe attack of chorea She was surrounded by a group consisting of her mother and some neighbours who were endeavouring to hold her still, being afraid that in the violence of her movements she might break one of her limbs The mother stated that on the previous day the girl was perfectly well until the evening She had been in bed and asleep for over an hour when her mother, hearing her call out, went into the room and found her in what she thought was a fit, throwing herself about the bed and wildly jerking her limbs She also complained of pain in her right leg but this soon passed off I was not able to gather exactly how long this attack lasted but I should judge that it continued for about half an hour, the girl then went off to sleep for the rest of the night In the morning she seemed much better and got up She ate well, played about and even helped to wash up the tea things On questioning the mother closely, however, I found that all day she had noticed occasional twitchings of the girl s face accompanied by jerky movements of the arms and the legs At about 8 P M on that day—namely, Dec 18th—she was again seized with the violent choreic movements and on my arrival at 10 30 P M was in the state which I have described above With great difficulty I listened to her heart but could hear nothing abnormal This condition of most violent choreic movements, during which the girl did not keep still for a moment, lasted until about 1 P M, on the 21st when she suddenly became absolutely quiet, gradually sinking and dying at 5 P M So violent were the movements that the skin over the legs, the elbows and the backs of the arms was rubbed quite raw The child managed to take nourishment well up to the morning of the day of her death but she had had practically no sleep since the night of the 18th The treatment consisted of abundant fluid nourishment with four minim doses of Fowler s solution and five grains of bromide of potassium

I have no reason to doubt the mother s statement as to the suddenness of the attack, though I find that the father had noticed a slight twitching of one shoulder for two or three days previously On Dec 15th I was at the house seeing a younger brother who was suffering from a slight attack of bronchitis and I then saw the little girl playing about apparently quite well Could fright have been the cause of this attack? I find that the child had had two definite attacks of fear The first occurred one night in the previous week when her younger brother with whom she was sleeping had a violent fit of coughing both she and her mother fearing that he was choking with the phlegm The second occurred on Dec 16th in the following circumstances She had gone to the house of a neighbour, who was bringing back the medicine for her brother This woman has an epileptic girl who is a gibbering idiot and apparently the two children sat and stared at each other until the mother of the epileptic appeared with the medicine When asked by her father on the night of Dec 18th whether she had been frightened she mentioned this epileptic s name

Littleport, Cambridgeshire

A CASE OF PERNICIOUS ANÆMIA SHOWING MARKED IMPROVEMENT UNDER ARSENIC AND BONE MARROW

By John Brunton, M B Glasg, M R C S Eng

THE treatment of pernicious anæmia affords so many depressing experiences that it may be of interest to record a case of more hopeful significance The patient a woman, aged 55 years, first came under observation in October 1903

---

[1] Transactions of the Obstetrical Society of London vol xxxvi 1894 p 3.

[2] Congenital Affections of the Heart 1894 pp 23–28

[3] Lyon Médicale vol lxxxvi, 1897 p 155

She was then confined to bed with extreme weakness and according to her statement had been gradually losing strength for about two years. The diagnosis presented no difficulty. The lemon-yellow tint of the skin, the extreme pallor of the mucous membranes, the œdema of the legs, the retinal hæmorrhages, and a temperature ranging irregularly from 97° to 102° F. left no room for uncertainty and the examination of the blood supported the diagnosis. After treatment for a week with small doses of Fowler's solution the case was seen in consultation with Dr. C. O. Hawthorne. A very grave prognosis was unavoidable as the patient was in a most feeble condition and it was suggested that bone marrow should be tried. This was given at first in the fresh state and afterwards as tablets of bone-marrow extract. The effect was very striking. In the course of a month the severe character of the symptoms had been very favourably modified and after three months' treatment there was little to show that the patient had been seriously ill. Unfortunately, in May, 1904, there was an attack of pleurisy with congestion at the base of each lung and from this time the patient was quite unable to retain arsenic in whatever form presented. Gradually the former symptoms returned and she died somewhat suddenly near the end of July.

The interest of the case centres in the fact that even after the patient seemed quite beyond hope she improved under treatment to such an extent that she enjoyed some six months of comfortable and relatively active life.

LONDON TEMPERANCE HOSPITAL.

TRAUMATIC HYDRONEPHROSIS AND TRAUMATIC PLEURAL EFFUSION; ASPIRATION OF BOTH EFFUSIONS; RESECTION OF RIB; RECOVERY.

(Under the care of Sir William J. Collins.)

For the notes of the case we are indebted to Mr. J. S. Hosford, surgical registrar.

A boy, aged 13 years, was admitted into the London Temperance Hospital on May 23rd, 1903. He had been riding behind a cart and slipped off, when a passing omnibus ran over his abdomen. On admission, though suffering from shock, he was conscious and complained of great pain and tenderness on the left side of the abdomen in the ilio-costal space. He was well nourished, the skin was swarthy, and there was ecchymosis of the skin forming a broad band stretching from the left ilio-costal region to the right hypochondriac region. On palpation there was great tenderness over the left renal region but no swelling or abnormal dulness was detected. He easily passed urine, which was free from blood but contained a little albumin. There was no evidence of fracture of the ribs.

For the first three days after admission the temperature was above 100° F. and the amount of urine was less than a pint a day. On May 27th the temperature rose to 102°, the pulse was 120, and he had pain over the left side of the chest and there were marked tenderness and some resistance in the left hypochondriac and lumbar regions. On the 31st the temperature was over 103°. There were dulness and tubular breathing over the lower half of the left chest. The amount of urine had been 50 ounces a day. There was more defined swelling in the left renal region and the stomach note was loud between this and the dull thoracic area. (The question of traumatic hydronephrosis or ruptured spleen, complicated with pleural effusion, was discussed by Sir William Collins.)

On June 11th the exploring syringe drew sanious serum (sweet) from the seventh left space in the mid-axillary line. On the 12th, under chloroform, Sir William Collins inserted an aspirator in the left ilio-costal space and drew off eight and a half ounces of sweet mauve-coloured acid fluid of specific gravity 1012. On the 19th the amount of urine had been about 30 ounces a day. The temperature was rather hectic in type. The left chest was aspirated in the sixth space and 30 ounces of sanious fluid were withdrawn which spontaneously coagulated. On the 26th, under chloroform, Sir William Collins resected two inches of the left sixth rib, evacuated several ounces of pus from the left pleura, and inserted a tube. No return of the lumbar swelling appeared and the amount of daily urine increased to from 35 to 50 ounces. On July 12th a small collection of pus was found and opened at the left base posteriorly.

The boy had undergone considerable emaciation since admission but from this time forward he began to put on flesh and the chest symptoms gradually resolved. He gained a stone in weight during August. The tube was left out on Sept. 15th and he was discharged to a convalescent home on Oct. 7th. He has since presented himself for examination and is fat and well, the chest shows no abnormal signs, and there is no abdominal swelling to be felt. The urine and the temperature were normal.

Remarks by Sir William Collins.—In this case trauma of the left hypochondrium, without fracture of the ribs, led to the effusion of two distinct and different collections of fluid, one above the diaphragm pleural in situation and becoming purulent, the other below the diaphragm, acid, of renal origin and disappearing after one aspiration. This latter collection I regarded (after dismissing the possibility of ruptured spleen) as one variety of "traumatic hydronephrosis," such as I described fully in 1892.[1] Probably the case was not merely one of hydro-renal distension from ureteral blockade, but the collection might have been in part external to the renal capsule and circumscribed by the perirenal fat.

BRADFORD ROYAL INFIRMARY.

TWO CASES OF HERNIA OF THE CÆCUM.

(Under the care of Mr. W. H. Horrocks.)

For the notes of the cases we are indebted to Dr. F. W. Schofield, house surgeon.

Case 1.—The patient, a man of medium build, aged 42 years, a mechanic, was admitted to the Royal Infirmary, Bradford, as an emergent case, on May 30th, 1904. He complained of a rupture on the right side which was giving him severe pain. It came down in the early morning and he had not been able to reduce it. He had had the rupture for five or six years. The cause of it was not known. It had come down every morning when he got up and had gone back at night when he lay down. He had not worn a truss. During the six weeks previous to admission he had pain from the rupture which prevented him doing his work. He had not had any trouble from it before this. His previous health had been good. He had never been troubled with a cough and there was no history of any injury. The hernia was a complete scrotal hernia on the right side of about the size of the closed fist. There was an impulse on coughing, manipulation was painful, and the rupture was not reduced at once. It went back soon after an icebag had been applied when he was in bed. The inguinal ring was very patent. Radical cure was performed. The sac wall was found to be very thick. The sac was continuous with the tunica vaginalis. On opening the sac the upper part was found to contain the last part of the ileum and the commencement of the cæcum. This part of the gut was adherent to the back of the sac. The sac was cut across and the upper part was reduced with the attached gut.

Case 2.—The patient, a man, aged 52 years, was admitted to the infirmary on May 5th, 1904, complaining of rupture on the right side, giving him pain when he lifted things and when he walked long distances. He said it had been down for three months without going back. He had been ruptured for 14 years. During the last 12 months he had a cough and this caused pain in the rupture. He had had a fractured thigh 16 years ago. The hernia was large right-sided scrotal with a distinct impulse on coughing. There was a tympanitic note on percussion. The external ring was of large size. The hernia was easily reduced but very readily came down when the patient coughed. He had a long prepuce. Operation was performed on May 10th, 1904. On opening the sac, the wall of which was very thick, it was found to contain the cæcum, appendix, and lowest piece of the ileum. The cæcum was covered in front and at the sides by the thickened hernial sac. The cæcum had no mesentery but was attached by a thick fleshy pedicle to the back of the canal. From the lower part of the cæcum a fleshy band covered by tunica vaginalis descended to the upper part of the testicle. The upper part of the sac after being sutured was reduced with the gut. The testis was removed. The inguinal canal was closed by buried sutures. Both patients made uninterrupted progress and were discharged cured.

---

[1] Brit. Med. Jour., April 30th, 1892.

Remarks by Mr. HORROCKS.—The reports of these two cases well illustrate the two kinds of cæcal hernia described by Scarpa. In the first the presence of the cæcum is accidental. It has no special vascular connexion with the hernial sac and beyond the facts that the sac is usually thicker and the cæcum and appendix more liable to form peritoneal adhesions it does not differ from an ordinary enterocele. In the second case the vessels to the cæcum run in behind the cæcum and any attempt to separate them is liable to cause gangrene of the gut. The broad fold connected with the testis suggests the descent of the testicle as a cause of the low position of the cæcum. In both cases there was a well-marked hernial sac but in the second case this was deficient behind and below, the cæcum being sessile. The treatment of these varieties of cæcal hernia differs. In the first case, "accidental cæcal hernia," the ordinary methods of radical cure are effectual. In the second case the treatment is castration and separation of the fleshy tissues at the back of the sac and reduction of the cæcum. The inguinal canal may then be obliterated by several stitches through the fibres of the transversalis and oblique muscles. In a case recorded by Sir F. Treves[1] this method was adopted. The object of these remarks is to draw a clear distinction between these two kinds of cæcal hernia and to emphasise the necessity of different treatment.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Some Changes which take place in the Lungs and the Pleura, chiefly in Pulmonary Tuberculosis, as shown by Skiagraphy.

A MEETING of this society was held on Jan. 10th, Sir RICHARD DOUGLAS POWELL, Bart., the President, being in the chair.

Dr. DAVID LAWSON demonstrated Some Changes which take place in the Lungs and the Pleura, chiefly in Pulmonary Tuberculosis, as shown by Skiagraphy. He introduced his subject by showing the difference in the behaviour of serous fluid and serous fluid plus air in a rubber bag as exhibited by skiagrams. The upper border of the fluid in the bag from which air had been exhausted appeared ill-defined and concave on account of its capillarity, while that of the fluid in the air-containing bag was sharply defined and horizontal. The same difference was demonstrated between ordinary serous pleural effusions on the one hand and cases of hydro- or pyo-pneumothorax on the other. The x ray appearances of a pyo-pneumothorax four hours before operation and again three months and nine months later when the lung had fully expanded were exhibited by means of skiagrams thrown on the lantern screen. In the same way it was shown that in certain cases of pleural effusion the lung above the level of the fluid had undergone some compensatory emphysema, while in others there was the common association with an intrapulmonary apical lesion. The comparative appearances of collapsed lung, of thickened pleura, and of dry pleurisy were also demonstrated and the points of skiagraphic diagnosis between the foregoing conditions and that of pulmonary consolidation and cavitation were discussed. Dr. Lawson referred, too, to four instances of primary infiltration of the middle third of a lower lobe, the upper lobe on the same side remaining either apparently unaffected or, if not so, then only affected at a later date and to a minor extent, and pointed out the unfavourable prognosis presented by these cases. A striking instance of post-mortem corroboration of skiagraphic appearances was afforded by the comparison of a radiograph taken during life with a photograph of a lung after death in which four [illegible]

Dr [illegible] pres[illegible] in a case of pyo-pneumothorax and recounted a case of pulmonary disease in which skiagraphy had been of service. He considered that the failure of a certain part of the lung to light up on deep inspiration was probably of importance in the early diagnosis of pulmonary tuberculosis. In his opinion pus produced a denser shadow than serous fluid.

Dr. J. E. SQUIRE emphasised the importance of skiagraphy as a means of making a permanent record of thoracic conditions at one time for comparison with those which obtained at another. He doubted whether skiagraphy enabled an earlier diagnosis to be made than was afforded by physical examination.

Dr. T D. LISTER did not believe that skiagraphy was of importance in the diagnosis of pulmonary conditions.

Dr. J. KINGSTON FOWLER expressed his belief that in the majority of cases of early pulmonary tubercle physical signs were of greater value than the x rays. In cases of aneurysm he had found the latter of advantage.

Dr. F. RUFENACHT WALTERS referred to certain cases of pulmonary disease in which skiagraphy had not been utilised but in which he believed its use might have been interesting if not instructive.

Dr. LAWSON replied.

MEDICAL SOCIETY OF LONDON.

Functional Insanity and Allied Neuroses.—Encephalitis and its Relation to Acute Anterior Poliomyelitis.

A MEETING of this society was held on Jan. 9th, Mr. JOHN LANGTON, the President, being in the chair.

Dr. ROBERT JONES read a paper on Functional Insanity and Allied Neuroses. He defined function and included in his consideration the functions of the neuron. He referred to the fact that the function of many organs changed without leaving evidence of alteration in structure. Tumultuous cardiac disturbance followed upon a shock of surprise, albuminuria occurred without disease of the kidneys, and, similarly, mental perversion occurred with bodily disorders without any structural brain disease. The mental irritability and the impulsiveness of cardiac disease, the hopefulness accompanying pulmonary tuberculosis, and the different mental states accompanying digestive disorders, gout, and so on were instanced. In his definition of insanity Dr. Jones [illegible] negation of sanity, which definition included every variety of mental abnormality. There was no standard of health, which was a variable state, and therefore no standard of insanity, as the age of *the individual, his position in society, and* the period in which he lived were all qualifying conditions. The presence of illusions, hallucinations, and delusions was not necessary i[illegible] many men [illegible] capable of [illegible] themselves [illegible] criterion of [illegible] temporary delirium of febrile states resulting from disordered nutrition and mentioned cases of scarlet fever, typhoid fever, and pneumonia which had been admitted under his care into the asylum as cases of insanity, in which the patients [illegible] whom [illegible]. He [illegible] sanity, [illegible] forms of dementia, certain neuronic changes occurring in acute delirium, and the deficiency of the development of pain observed in cases of idiocy and imbecility, there was no means of [illegible] logical findings, and it mig[illegible] was at the present time no [illegible] many mental abnormalities were described as "disease manifestations" rather than actual disease. Dr. Jones referred to the physiology of the neuron and acknowledged the great work of Ferrier, Horsley, and others who endeavoured to investigate the actual material and quantity of nervous energy; but, in spite of so much progress, little more was known at present than its rate of transmission or conduction along a nerve.

---

[1] Brit. Med. Jour., 1887.

He also referred to the pathology of the neuron and indicated that poisons circulating in the blood attacked the fluid nutritive protoplasmic substance of the nerve cell and, with the possible exception of the tetanus toxin, no other poison attacked the fibrillar substance or the stereoplasm of nerve cells, demonstrating, pathologically, the possibility of functional rather than organic or structural disease. Dr. Jones referred to the evolution of insane ideas, remarking that the most highly evolved but less organised of the senses, such as sight and hearing, contributed more to insane delusions than did the more stable but less informing senses of smell and taste. He showed how tactile sensations were associated with hysteria, whereas auditory and visual sensations were more often associated with insanity, and that hysteria was a "lower-grade" insanity. In hysteria sensory disturbances resulted in motor activities; in insanity action followed delusions—a disturbance of the highest intellectual processes. He considered that much of insanity was functional, which appeared to be supported by the fact that 53 per cent. of all women admitted during 1903 into the asylums of London under the age of 25 years were discharged recovered within the year and in most cases thus discharged recovery took place under six months. Dr. Jones considered that the majority of cases of insanity among women were related to the emotions and were also of a transitory type. He referred to the loss of memory in normal persons, in cases of hysteria, and in insanity and claimed that the same paths and the same mechanism were at work in health and in functional abnormalities. He referred to cases of "double consciousness" and their sudden recovery, also to cases of post-epileptic automatism, both being probably functional, and he related cases of loss of memory under his care in which the condition completely and suddenly passed off. Dr. Jones next dealt with hypochondriasis, neurasthenia, epilepsy, paramyoclonus, and chorea and pointed to an absence of structural lesions in these cases. He also referred to astasia abasia as functional modifications in systematised areas of action. The mental condition accompanying pregnancy was another example of functional mental disturbance. He placed great stress upon the heredity of nervous diseases and urged that it was not diseases or ideas that were transmitted but a proclivity or a tendency to disease in adverse circumstances. He pointed out how necessary early treatment was in all functional mental states and that long-continued functional abnormality might become organic, as was exemplified when long-continued electrical stimulation of a cranial nerve caused nuclear changes; also that environmental states were important, as minute variations acting for long periods upon the most slowly growing of all the organs of the body might cause distressing disturbances, making it possible for functional mental abnormalities to end in incurable organic insanity.—Dr. C. A. Mercier said that the question which this paper raised was not so much whether such a condition as functional insanity existed as whether there was any form of insanity which was not functional. He said that normally at regular intervals of the 24 hours the mind was wiped out by the occurrence of sleep. So in insanity portions of the nervous system became functionless but these periods occurred at irregular and not at regular intervals. A functional insanity was one in which no structural alteration in the brain could be found and he was inclined to regard all insanity as functional. Cells might be found to be damaged but these could not be connected with the hallucination and illusion which occurred. It was the remaining portion of undamaged cell which produced the symptoms and in this sense he regarded all insanity as functional.—Dr. T. B. Hyslop dealt with the difficulty of distinguishing certain cases of neurasthenia from cases of general paralysis of the insane. He considered that it was important to endeavour to find out the lesion giving rise to the symptoms in any case, as this alone formed a basis for progress.—Dr. W. L. Andriezen considered there was no evidence of functional insanity. He stated that he had found areas of cortical sclerosis in cases of epilepsy. He did not regard the post-epileptic alteration of personality as functional in nature. He referred to the periodic attacks which occurred in dipsomania and to periodic attacks of melancholia which might persist for many years. These he considered as due to some maldevelopment or malnutrition which allowed the cerebral mechanism to become faulty.—Dr. Jones replied.

Dr. F. E. Batten read a paper on Encephalitis and its Relation to Acute Anterior Poliomyelitis. He said it was generally recognised that some cases of acute hemiplegia occurring in children were due to the same causes and had the same pathology as cases of acute anterior poliomyelitis. It was not, however, generally recognised that portions of the brain other than the motor path might be affected in a similar manner and give rise to a variety of symptoms. He said that cases presenting symptoms of acute intracranial disease frequently occurred during the summer months of the year. These cases were like anterior poliomyelitis, acute in onset, often in the early stage of the disease giving rise to extensive paralysis which in part rapidly cleared up, leaving more or less permanent paralysis. Convulsions were present in some cases. He said that these cases of encephalitis corresponded not only clinically and pathologically to acute anterior poliomyelitis but also in their seasonal relationship. He divided the cases according to the portion of the brain affected into three groups: (1) those cases in which the cerebral hemispheres were affected; (2) those cases in which the cerebellum was affected; and (3) those cases in which the cranial nuclei were affected. The symptoms varied according to the situation of the lesion. In affections of the cerebral hemisphere the lesion might affect the whole of one hemisphere or might limit itself to the frontal region, the Rolandic region, or the occipital region. The affection of the cerebellum might be unilateral or bilateral. In the affection of the cranial nuclei one or more of the cranial nuclei might be affected. The affections of the cerebrum and the cerebellum were described under the title polio-encephalitis superior, whilst affections of the cranial nuclei were described under the title polio-encephalitis inferior. He then proceeded to give instances of affection of the various portions of the cerebral cortex from cases which had for the most part occurred during the summer of 1904. After dealing shortly with the instances of affection of the frontal and the Rolandic region of the brain, the latter of which was the most common manifestation of the disease, he described a case in which there was evidence of affection of the occipital lobes. In this case the child was completely blind for three weeks without any other sign of ocular disease. From this the child gradually recovered completely, save for the fact that the child remained subject to attacks of *petit mal*. He then gave instances of affections of the cerebellum, both unilateral and bilateral, and finally instances of affections of some of the cranial nuclei. Passing then to the pathology of the disease he said that although recovery had taken place in all the present series of cases, yet in a former series he had been able to prove the pathological condition in two cases: in one case of hemiplegia in which the cortex of the left side was affected and in another in which the nucleus of the seventh nerve was affected on the right side. He then dealt with the seasonal relationships of the disease and pointed out that these cases of intracranial disease were more common during the summer months of the year. He had collected the cases of acute anterior poliomyelitis which had occurred during the summer of 1904 and he had met with 29 cases of anterior poliomyelitis and eight cases of polio-encephalitis. Much more pathological evidence was required on this point and he hoped at some future time to make his series of cases as complete pathologically as they were clinically.—Dr. C. E. Beevor said that the view held with regard to these cases of sudden hemiplegia in children was that they were due to thrombosis of the larger veins. He thought that considerable evidence had been brought forward pointing to the fact that the cause of this condition was thrombosis of the finer vessels.

SOCIETY OF ANÆSTHETISTS.

The Vernon-Harcourt Inhaler.

A MEETING of this society was held on Nov. 4th, 1904, Mr. C. Carter Braine, the President, being in the chair.

Mr. Edgar Willett, who opened a discussion on the Vernon-Harcourt Inhaler, said that he had now used it for over 250 cases and in selected cases in his hands it had given a satisfactory anæsthesia. In the large majority of cases he started the anæsthesia with nitrous oxide gas and ether and after some four or five minutes went on with the inhaler. He had done this because he found that it saved time and because in one case serious symptoms of syncope from chloroform, which disappeared under ether, had occurred. He had also found Mr. Harcourt's "increase tube," which allowed of the strength of the chloroform vapour being increased to 3 per cent., of great use and with it he was but rarely obliged to discard the apparatus for some other. Of course, there were a large number of cases where the inhaler could not be used but apart from these he had found that the inhaler answered to all the ordinary requirements where ether was contra-indicated.

Dr. H. MACNAUGHTON-JONES and Mr. WALTER TYRRELL also spoke in favour of the apparatus.

Mr. PERCY W. G. SARGENT had seen the apparatus in use in the hands of a number of anæsthetists for a variety of surgeons, including himself. He was forced to say that from the operator's point of view it was not satisfactory. The induction took a longer time than could be spared by a surgeon with a long list of operations before him, while the anæsthesia was in a large number of cases too light and "reflex movements," movements that required controlling by dressers, were far too common. Where the anæsthetist started with ether he readily understood that the inhaler was more successful, as the initial incision was made while the patient was under the influence of that drug.

Dr. J. BLUMFELD said that after considerable use of the inhaler he had formed definite conclusions as to its value. Such instruments might be regarded from two points of view, the purely physiological or the clinical. He dealt entirely with the latter aspect. There were certain disadvantages in the use of the inhaler which should be mentioned. Cases of operation about the face or the neck were obviously instances in which the apparatus could not be used; in addition there were many cases in which the condition of the patient rendered a perfect result impossible of achievement in a reasonable time. Thus on several occasions in abdominal operations he had discarded the instrument because of the unsatisfactory relaxation of muscles. He was of opinion that for general use an inhaler must have a wider applicability than was the case with this one and that it was the duty of anæsthetists to obtain the best results and to teach others to obtain them with the simpler forms of apparatus. He fully realised the importance of accurate and small dosage in the use of chloroform but he did not agree that it was only to be obtained by the use of this inhaler. He considered also that it had defects with regard to the possibility of observing absolute cleanliness in all its parts and also as regards the ease with which accidental complications in the apparatus might arise.

Dr. DUDLEY W. BUXTON pointed out that they were there to obtain the results of the experience of anæsthetists who had used the inhaler and not to discuss whether a 2 per cent. chloroform vapour was sufficient for all the exigencies of surgery. The "regulator" was graded for this percentage but it could equally well be arranged for higher percentages if such were required. The arguments advanced against the inhaler [illegible] (1) [illegible] (2) that it p[illegible] it was u[illegible] accurate [illegible] could say that he had met with no deaths and no dangers, though reports to the contrary had been hinted at. If a greater depth of narcosis than was represented by the third degree of Snow, the true surgical anæsthesia, was required, then either a greater length of inhalation or a higher strength than 2 per cent. could be obtained by employing either a larger bottle or the accessory tube. The statements about increased percentages being caused by alterations in the depth or the frequency of respiration had been discussed by Mr. Harcourt and his answers to the criticism were conclusive. His (the speaker's) clinical experience went to show that both the changes in respiration due to "respiratory storms," which could only occur during incomplete anæsthesia—i.e., in the induction stage—and the alleged dangerous increase in percentage due to "slopping" of the chloroform in the bottle when it was shaken were negligible. He had never seen any symptoms of increased narcosis, which must have arisen if any considerable rise in the percentage of chloroform had been inhaled. Of course, care must be taken to avoid shaking but even raw students were soon enabled to acquire this heedfulness. The immense value of this inhaler lay in the fact that the person using it who would be watching his patient, knowing what depth of narcosis was required, was able to regulate to a nicety the dose given. He was convinced that a more extended use of the apparatus in the hands of those whose experience had been unfavourable would give better results.

Dr. J. F. W. SILK stated that though he had had no experience of the inhaler himself he felt that he was justified in forming an opinion founded on the very full description of other anæsthetists' results. It was obvious to everyone at the outset that its use was a limited one, as Mr. Willett had made it abundantly clear that it was not suitable for infants, operations about the mouth, and abdominal operations where full muscular relaxation was required. In such circumstances he considered that it was not a suitable instrument with which to teach students, as they could not be instructed in those classes of cases which were peculiarly suitable for the administration of pure chloroform. Further than that the long time that was required for the induction, so far as hospital work was concerned at any rate, made it necessary that the induction should be by nitrous oxide gas and ether. He also condemned it on other grounds. Its safety had been alleged but he pointed out that with the death-rate from chloroform, taken all round, at 1 in 3000 it was a little premature to make dogmatic statements from figures which only amounted to hundreds of administrations, and those in the hands of specialists, among whom the death-rate was far lower than the figure he had mentioned. As regards the machine being a regulating one, he had seen the rise and fall of many of these instruments and they had all failed because they were too complicated for ordinary use, and though the present one was an improvement as regards the accuracy of the regulating, that had been obtained by still further sacrifice of simplicity. He himself preferred to regulate the dose by the requirements of each individual case and not by the theoretical percentage that was thought to be sufficient.

Sir VICTOR HORSLEY spoke very highly of the inhaler, considering that it marked a great advance on the usual haphazard methods of giving chloroform. He had seen it used in a great number of cases of his own and always with a satisfactory result after the administrator had mastered the instrument. It enabled the latter not only to know exactly what amount he was giving at any particular moment but also [illegible] As regards those cases where there [illegible] of abdominal muscles, he thoug[illegible] should not be aimed at, as that indicated a dangerous amount of narcosis.

Mr. H. C. CROUCH said that no report of the inhaler as used by former speakers was of any value; he had used the inhaler unclamped and had seen that the amount of shaking completely destroyed the intentions of the inventor, as the percentage of chloroform was obviously increased to a dangerous extent. It was idle for Dr. Dudley Buxton to say that the inhaler did not shake; the only way scientifically was so to fix it that it could not shake. He had done that and he found that the result was very different from the results with it unclamped. Sir Victor Horsley had said that it was an enormous advantage to know the amount of chloroform that was given. He agreed, but that was precisely what was not known with the Vernon-Harcourt inhaler, as with the indicator at 2 per cent., even in the clamped instrument, the anæsthetist might be giving 1·3 per cent. or 2·3 per cent. and he could not tell which. He was amused to see that the supporters of the apparatus had now given up the 2 per cent. limit as insufficient and had found that the "increase tube," which allowed of a nominal 3 per cent. to be given, was often necessary.

Dr. A. G. LEVY said that it was not necessary violently to splash the chloroform in order to raise the percentage of vapour, an appreciable increase of vapour being produced by the gentlest possible oscillation of the bottle, an extra surface of chloroform being thus presented by reason of the wetting of the sides of the bottle. During the transfer of the patient from the anæsthetising room to the operating theatre he had seen the bottle swaying sufficiently to produce a 5 per cent. vapour. It was significant that an excess of vapour was thus yielded at the moment when it was most necessary. Sir Victor Horsley had stated that a 2 per cent. vapour was sufficient for all purposes. Such a statement as evolved from the use of the Vernon-Harcourt inhaler could not be accepted in view of the inaccuracies of this instrument. When using an apparatus which eliminated these errors he found that 2 per cent. was quite insufficient. As the Vernon-Harcourt apparatus possessed sources of excess of vapour it was logical to assume, therefore, that more than 2 per cent. was administered in cases in which it was successfully used. He did not mean to suggest that the bottle was intentionally shaken, the normal oscillation of the bottle and that consequent upon the application of the hand to the bottle in warming it being sufficient to insure an efficient strength of vapour in the majority of cases. With regard to the large variations admitted to be consequent upon fluctuations in the strength of the breathing, Sir Victor Horsley had explained these errors away by saying that whilst weak breathing gave a higher percentage it also resulted in a lower dosage (less total chloroform per minute). This argument did not affect the innate fact that the apparatus did not evolve the percentages it registered; and moreover Sir Victor Horsley's dosage theory still required substantiation—it did not appear to be in conformation with prevalent views.

Dr. DUDLEY BUXTON, in the absence of Mr. Willett, replied. He said that most of the speakers had had little or no experience of the apparatus; theirs were pious opinions which lacked conviction. [illegible] hing that Sir Victor Horsley had said. [illegible] only say that Mr. Willett's limitation of cases was due to the fact that that gentleman held ether to be a safer anæsthetic than chloroform and so he employed it whenever it was possible. He (the speaker) used the inhaler for children (the faces of infants were not suitable for closely fitting masks) and for operations about the mouth until anæsthesia was established when he had recourse to a mouth tube and a Junker's inhaler. Mr. Crouch's remarks had been already dealt with. He believed that Dr. Levy's objections were more academic than real. In all cases the chloroformist must be alive to clinical phenomena and must meet the indication of the case. This was provided for by the valve in the Vernon-Harcourt inhaler. The period of induction was from eight to ten minutes and this was a shorter time than was required by the surgeon for his preparations. Where time was important the ethyl chloride-ether-chloroform sequence could be used.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Artificial Respiration.—Exhibition of Patients and Specimens.

A MEETING of this society was held in the large theatre of the Royal Infirmary on Dec. 21st, 1904, and partook of the nature of a clinical demonstration of patients. Dr. J. O. AFFLECK occupied the chair.

Professor E. A. SCHAFER gave a demonstration of his method of Artificial Respiration. The patient was placed in the prone position and the operator kneeling on one side rhythmically compressed both sides of the chest with each hand. By this method artificial respiration could be kept up for a long time as there was little fatigue to the operator. The prone position was very advantageous in that it allowed water and mucus to drain naturally away from the patient; the tongue also had no tendency to fall backwards into the throat as it was apt to do in the supine position. There was also little or no risk of fracturing the ribs as frequently happened in Howard's method. In cases of asphyxia the liver was generally enormously swollen and with the patient in the supine position it was very easily ruptured, and indeed this accident frequently happened in ordinary attempts at artificial respiration. By having the patient in the prone position more air was allowed to gain entrance to the lungs as the pressure was spread over a wider surface and more equally than it was in the supine position, when the pressure was exerted over a limited area on each side.

Dr. W. ALLAN JAMIESON exhibited: 1. A man who had suffered from an extensive Tertiary Serpiginous Eruption and who showed the advantage of combining local with constitutional treatment. The patient had had no reminder of syphilis for 27 years, then this eruption appeared on his back, chest, abdomen, the inner sides of the thighs, and the arms. It was evidently of the nature of a serpiginous gumma which spread widely showing crusts and slight ulceration. The man was admitted to the Royal Infirmary in June, 1904, and under potassium iodide the condition improved. He was, however, re-admitted in the following September as the eruption had again extended very widely. The whole area was scraped with a sharp spoon repeatedly. A starch paste with a small quantity of calomel was then applied while iodide of potassium and carbonate of ammonium were administered internally and the result was successful under this combined treatment. 2. A case of Lichen Planus exhibiting peculiar colouration. The patient was a cab-driver, aged 51 years. He had suffered from gonorrhœa in 1881 and soft sore with suppurating bubo in 1882 but there was no history of syphilitic infection. He was admitted on Dec. 8th, 1904. The eruption first appeared on the inner side of the left knee in the shape of small pink spots. This then spread over the abdomen, the flanks, and the arms and there was much itching. This eruption was now represented by brownish spots. On section the microscopic appearance was that of a retrogressing lichen planus.

Dr. NORMAN WALKER showed two men suffering from Keloid over the usual site, the front of the chest. Both had been treated by the x rays and had greatly benefited, the pain having almost immediately disappeared. Two cases of Lupus of the face in women were also shown to demonstrate the permanent results of treatment by the x rays. In one case the patient first presented herself in June, 1901, and had been subjected to many exposures. The last exposure was, however, in May, 1903, and so for an interval of 18 months she had had no treatment and yet the improvement had persisted. In this case the everted mucous membrane of the eyelid had been changed into skin. In the second case 107 exposures had been made.

Dr. DAWSON F. D. TURNER showed: 1. A case of Tic Douloureux treated by static electricity. The case occurred in a woman who could get no sleep on account of the pain; there were twitching of the face on the left side and numbness. She was deaf on the affected side and had had all her teeth removed without benefit to the condition. The static breeze which had been commenced on Nov. 8th had proved of the greatest benefit in this case. 2. A case of Epithelioma of the Lower Lip in a man which had been treated by radium and then by the x rays. He had had exposures to radium on 17 days amounting in all to about eight and a half hours' duration and then subsequently the x rays. His condition showed a marked improvement. 3. A case of Flat-foot produced by the traumatism of jumping from a vehicle. The sinusoidal current had been applied to the foot in a foot-bath, with the result that the foot [illegible] and the pain had entirely gone. Dr. [illegible] the sinusoidal current found its best application in paretic conditions. 4. A case of Non-healing Ulcer situated over the external malleolus of the right foot. The ulcer had come and gone during the past two years. By the application of the x rays twice a week for four minutes the ulcer had entirely healed. 5. A woman with a Chronic Varicose Ulcer over the lower part of the left leg and to the inner side. The x ray treatment had done much good though the patient had not been laid up but had performed her usual house duties all day.

Dr. J. W. B. HODSDON showed a child, aged three years, on whom he had performed Primary Disarticulation of the Right Hip. The child had been run over by a car which caused a complete fracture as well as a greenstick fracture of the femur. The importance of the case lay in the remarkably beneficial effects which resulted from the intravenous injection of saline fluid and adrenalin extract. The child's pulse was 200 and after the injection of one pint of sodium chloride solution and 30 minims of adrenalin chloride solution it at once fell to 120 and the condition of shock was recovered from. Its use quite replaced strychnine and stimulants.

Mr. C. W. CATHCART demonstrated two cases of Laminectomy for Paraplegia. 1. The first case was that of a man, aged 45 years, who had suffered during the preceding nine months from complete paraplegia. At first he had been treated for the pain in his back by rest in bed but without any benefit. On admission to the Royal Infirmary the conclusion arrived at was that there was pressure on the cord in the region of the tenth or eleventh dorsal vertebra. On opening the canal the cord was found to be compressed by a growth arising from the front. There was no tuberculous material in the canal. The laminæ having been removed distinct improvement was noted within three weeks although all the symptoms were aggravated for a few days after the operation. The operation was performed in March, 1903, and the man could now just stand alone and could walk by the aid of a go-cart. Previously to the operation he suffered intense pain in his back but now there was only a slight soreness. The case was probably one of tuberculous disease of the spine. 2. The second case was not a tuberculous one. The man first complained of a swelling at the back of the neck. An abscess developed there and was opened in March, 1904. In two or three weeks after this complete paraplegia of both arms and legs developed. Mr. Cathcart thought that there was an inflammatory swelling pressing on the cord in the cervical region. At the operation much granulation tissue was found underneath the laminæ. This was scraped [illegible]

nephritis. As he was getting weaker and emaciated and as the pain was chiefly complained of on the right side this kidney was cut down on from the lumbar aspect. The kidney was seen to be congested and swollen with certain spots of marked congestion and the surface was dotted over with yellow spots. It was evidently a case of septic nephritis and pyelitis. The pelvis of the kidney was incised and drained and at once the patient's temperature began to fall. He had steadily improved ever since the operation.

Dr. R. McKenzie Johnston exhibited a patient after operation for Extradural Abscess following mastoid disease. The girl was admitted on Oct. 3rd, 1904, and previously to admission had suffered from pain and rigors. On examination granulations and perforations were present in both ears. Her temperature rose soon after admission to 104° F. and she had rigors. It was thought to be a case of thrombosis of the lateral sinus though there was little or no swelling over the mastoid or displacement of the auricle. On cutting down, however, the mastoid cells were found to be softened and full of pus. These were scraped out and on chiselling upwards a small sinus was discovered with very fœtid pus and gas escaping from it. Working backwards the middle fossa was opened into and about two drachms of thin pus were evacuated. The lateral sinus was explored to the extent of three-quarters of an inch and was found to contain no blood but an organised white clot occupied its lumen. The interest of the case lay in the fact that the patient had been going about with a thrombosis of the lateral sinus. The girl had improved every day since the operation and was at present plump and healthy.

Mr. F. M. Caird showed: 1. A lad who, two years previously, had gone to the Edinburgh Royal Infirmary with Wrist-drop and Claw-like Contracture of the Fingers of the Right Hand. The elbow-joint had been fractured three years previously and the arm had been put up in splints. The condition simulated musculo-spiral paralysis but was really not so. It was an ischæmic contracture affecting chiefly the flexor tendons. The operation consisted in lengthening the flexors of the wrist and the fingers and the condition had very greatly improved. 2. A boy, aged six years, who had presented a very similar condition. The elbow-joint had been injured and had been treated by splints. The tendons in front and behind were operated on and the contracted condition had greatly improved. 3. A patient (male) after extirpation of the rectum and the anus by the combined abdominal and perineal route. The man, aged 68 years, had [illegible] carcinoma lasting four years [illegible] removed and the lower end of [illegible] ed in the mesial line in front. [illegible] l eight weeks previously and the patient had put on two stones in weight since. 4. A girl, aged 21 years, who had suffered from perforation of a gastric ulcer on two separate occasions. The first operation was performed on Sept. 22nd, 1903, 24 hours after the rupture. The ulcer was found situated on the lesser curvature and was of the size of a threepenny-piece. A slight hour-glass contraction of the stomach was then noticed. On Nov. 24th, 1904, she was again admitted and the operation was performed 14 hours after rupture. Many adhesions of the omentum were present and another ruptured ulcer was found of larger size than the previous one but in the same situation. The stomach showed a well-marked hour-glass contraction and as the suturing of the rupture contracted the passage too much gastro-enterostomy was performed and now the patient could eat any ordinary food.

Mr. H. Alexis Thomson exhibited a man, a tailor, who had suffered much from large gouty deposits on the areas of pressure—e.g., over the malleoli, elbows, and ligamentum patellæ. These had been removed and only one recurrence in the left elbow had shown itself. Many tophi were present [illegible] moved. [illegible] synovial [illegible] d pyorrhœa. Great improvement had resulted in his condition though it was generally stated that such deposits ought not to be interfered with.

[illegible] exhibited:— [illegible] of Enormous Horns growing [illegible]

Mr. J. M. C[illegible]: (1) [illegible]; (2) Two Cases [illegible] the Knee-joint; [illegible] and Liver from a case of Gastro-enterostomy.

Mr. Caird: (1) Rectum removed from the case described above; (2) a Tuberculous Kidney, with drawings illustrating the results gained by the Luys Separator; and (3) Stomach showing Posterior Gastro-jejunostomy and Lateral Anastomosis.

Society of Medical Officers of Health.—A meeting of this society was held on Jan. 6th, Dr. J. F. J. Sykes, the President, being in the chair.—Sir Lauder Brunton opened a discussion on the report of the Inter-departmental Committee on Physical Degeneration and pointed out that the fact of deterioration could be determined only by periodical and systematic measurements of children in schools. Medical inspection must be organised for the detection and relief of defects of vision and hearing and incipient constitutional disease. The physical education of children of both sexes should receive no less attention than the intellectual and the character of each should be to a great extent guided by the results of the medical examinations. School kitchens should provide means of instructing girls in the art of cookery while supplying meals at cost price to those who could pay and free to such as could not, the expenses being defrayed by voluntary effort or from the rates. Practical hygiene must be regularly taught and the schools themselves should be object lessons in health. The feeding of infants was a most difficult matter and on many grounds he did not approve of municipal milk depôts, preferring that the authorities should bring pressure on the large dairy companies to maintain a universally high standard of supply. He would not attempt to discuss the depopulation of the country by migration to the towns but expressed a hope that the authorities would some day consider any house "overcrowded" with more than two inmates to each room. Poverty, overcrowding, and physical degeneration were inseparably associated in causal relation. Medical officers of health must have [illegible] and the creation of [illegible] sirable. Failing this [illegible] an advisory council [illegible] thin whose province [illegible] fare of the nation [illegible] rations and including other scientific experts. The National League for Promoting Physical Education and Improvement was being constituted with a view to secure the organised coöperation of all existing associations and persons engaged or interested in the promotion of these efforts, and foremost among these he would place the medical officers of health throughout the country.—Sir John Gorst maintained that these conditions were well known to the officials of the Board of Education and that it was the duty of each one to press on the local education authorities, now the county and borough councils, the need for medical inspection at regular intervals; this, though it would not cure, would reveal the extent of the evils.—Dr. H. Franklin Parsons feared that free meals would not only pauperise the recipient but would lower wages.—Miss A. M. Anderson, chief lady inspector of factories, complained of the ignorance of the ladies who, with leisure and enthusiasm, offered their services as visitors. Girls of all classes wanted training in all that belonged to health which, under modern social conditions, they could not get from their mothers. The girls might be taught in evening schools but the instruction of the mothers must be provided by the medical officer of health.—Dr. J. C. McVail mentioned a school board in Scotland which had several houses of two and three rooms to which girls were drafted for a week or two at a time to learn domestic work. The depopulation of rural districts might be greatly checked by [illegible].—Dr. A. Newsholme [illegible] the money earned.—Dr. A. K[illegible] ratio observed in Edinburgh [illegible] the rooms from which the children came and their height, weight, and general intelligence. In the latter town the visitors provided meals at a cost charge of 1½*d.* a day to all who accepted the offer and found that such children made better progress than those fed at greater cost at home.—Dr. Kerr thought that the number of really half-starved children had been greatly exaggerated. But children must be looked on as future citizens from the physical side no less than from the mental; the appointment of school nurses in a few places had given the best results.—Dr. F. J. Allan said that he had received from a large staff of lady visitors valuable assistance after they had had the instruction that most of them greatly needed.—The President quoted figures showing the remarkable fluctuations in the infant mortality of different towns and after the discussion had been sustained by several speakers, medical officers of health and others, Sir Lauder Brunton replied. He pointed out that in Switzerland, where the State spent vast sums, greater than in any other country, on education, mostly free, very few children were fed at the cost of the rates and nearly as few by voluntary effort. He would say with the prophet, "My people are destroyed for lack of knowledge."

Glasgow Obstetrical and Gynæcological Society.—A meeting of this society was held on Dec. 21st, 1904, Dr. J. K. Kelly, the President, being in the chair.—The following specimens were exhibited:—Dr. J. M. Munro Kerr: Uterus removed by Vaginal Hysterectomy for Cancer of the Cervix complicated with Pregnancy. Cæsarean section preceded the vaginal operation.—The President: (1) Myoma of Uterus with Hæmorrhagic Degeneration; (2) Dermoid Cyst of Ovary; and (3) Ovarian Cyst.—Dr. J. Edgar: Mulberry Calculus from Ureter.—Dr. R. Jardine: Drawings of Corneal Opacities in Infants.—The business of the meeting was a discussion on the Treatment of Prolapse of the Uterus, introduced by Dr. W. L. Reid. Dr. Reid spoke first of the more chronic forms of prolapse, dwelling upon prophylaxis as very important. In milder forms of prolapse a pessary was often curative, more especially that of Albert Smith. When operative treatment was necessary the most suitable operation was that of amputation of the cervix with repair of the perineum together with anterior and posterior colporrhaphy. Fixation of the uterus to the anterior abdominal wall was also necessary in some cases. Dr. Reid said that he had no experience of paraffin injection in such cases.—Dr. Kerr was impressed with the disadvantages of the watch-spring pessary as becoming septic so quickly from the vaginal discharges. He also considered it of benefit to have a strong pelvic floor when repairing the perineum.—Dr. G. Balfour Marshall remarked that in cases of hypertrophy of the median portion of the cervix a pessary was of use in causing shortening.—Dr. Edgar had some experience of paraffin injection but considered it as somewhat dangerous owing to the risk of subsequent pulmonary embolism.—Dr. G. Scott MacGregor had tried paraffin injection once with failure.—Dr. C. C. Douglas spoke as to Martin's method of procedure.—The President remarked that he seldom performed a colporrhaphy when doing ventrofixation.—Dr. Reid replied.

Rochdale and District Medical Society.—A meeting of this society was held on Jan. 5th. Dr. D. Richmond showed five cases which had been operated on through the mastoid for Middle-ear Disease. All had suffered from discharge and deafness. One also suffered from attacks of giddiness and another from facial paralysis. The latter, a man, had had discharge from the ear for 20 years and was operated on by Dr. D. McKeown of Manchester. At the operation the sigmoid sinus was laid bare and appeared to be normal. A few days later the temperature became irregular and ten days after the operation the wound was reopened and the wall of the sinus was found to be indurated. It was freely exposed and excised after ligature of the internal jugular vein. The cavity was packed. Recovery was uninterrupted except for the formation of a large gluteal abscess. All five cases were cured by the operation. Three remained deaf, one recovered slight hearing, and one good hearing. The man who had Bell's paralysis had recovered almost complete power in the facial muscles. Dr. Richmond also showed a girl who had suffered from severe supra-orbital pain on the left side and also from what appeared to be hysterical fits. As the cause of the headache a diagnosis was made of blocking of the frontal sinus. The frontal region was trephined and a cyst was found containing from two to three drachms of clear fluid. The posterior wall was soft and yielding and the cyst seemed to be subdural. The lining was scraped and the cavity was packed with iodoform gauze. Granulation took place and in two weeks the wound was stitched. The patient had had no headache and no fits since the operation.—Mr. H. H. I. Hitchon, Dr. W. H. Carse, Mr. Wilton Mills, the President (Mr. W. Pooley), and others took part in a discussion on the cases.

Reviews and Notices of Books.

A Manual of the Practice of Medicine. By Frederick Taylor, M.D. Lond., F.R.C.P. Lond., Senior Physician to, and Lecturer on Medicine at, Guy's Hospital; Consulting Physician to the Evelina Hospital for Sick Children; Examiner in Medicine at the University of London. Seventh edition. London: J. and A. Churchill. 1904. Pp. 1065. Price 15*s.*

This manual is so well known that no words from us are necessary as to its general nature and scope. The work has been subjected to a very thorough revision since the last edition and considerable alterations and additions have been made. The sections on several subjects have been altered so as to include the results of the latest researches as to etiology, pathology, and treatment. In the section dealing with malarial fevers the relation of the mosquito to the malarial parasites is carefully considered and an interesting account is given of the changes which may be observed to occur in the organisms found in the blood of patients suffering from a pernicious form of fever. We notice that Dr. Taylor still employs the term "phthisis" as meaning "a destructive disease of the lung, brought about by the invasion of the tubercle bacillus." We have for some time past used the term "pulmonary tuberculosis" for such disease as being not only more exact but as indicating the site and the nature of the malady, and trust before long to see a general adoption of the term. A few remarks are made on the "sanatorium treatment," but these are so brief as to be practically valueless and no mention is made of one of the essential points—namely, the regulation of the patient's life according to his temperature chart. We quite agree, however, with Dr. Taylor's remark that for complete success the duration of the treatment must be very much longer than the period of three months for which it is sometimes prescribed.

In this edition many subjects are introduced for the first time into the book. A short account is given of Sleeping Sickness, the etiology being fully explained. Dr. Taylor is fully convinced as to the infection of patients by the glossina palpalis and as to the determination of the symptoms by the entrance of the trypanosome into the cerebro-spinal fluid. A brief description is given of Family Periodic Paralysis. The pathology is not definitely understood; the probability seems to be that some toxin is operating upon the muscular fibres. Some interesting observations have been made on the relations of the urine and of kreatinin-excretion to the attacks. In the section on Compression of the Spinal Cord some remarks have been added to the account of the diseases of the conus medullaris and the cauda equina. In discussing the diagnosis of these affections Dr. Taylor draws attention to the importance of seeking for the prominence of the spine which caries so frequently produces; at the same time he remarks that all the symptoms of compression may precede by several months the appearance of any projection of the spine. A section has been introduced on Diseases of the Thymus Gland. No mention, however, is made of the supposed connexion between atrophy of the gland and the marasmus of infants. In describing the disorders of nutrition which involve the bones and the joints the condition known as infective arthritis is discussed. In several of the infectious diseases, such as typhus fever and typhoid fever, influenza, pneumonia, septicæmia, and gonorrhœa, arthritis is found as a complication. Whether it is due in every instance to the specific organism of the disease or to a secondary infection is not always clear. Pulmonary osteo-arthropathy is also stated to be a form of multiple arthritis either of pyococcal or tuberculous origin. Another new section is that on Myelopathic Albuminuria, a name given by Dr. T. R. Bradshaw to a disease of the marrow of bones with which is associated the presence of albumin in the urine. The disease has probably in the past been confounded with mollities ossium.

It will thus be seen that Dr. Taylor's manual is still characterised by the thoroughness and the completeness which have stamped it throughout as a most excellent text-book both for students and for practitioners.

First Report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum. By the Director, ANDREW BALFOUR, M.D., B.Sc. Edin., M.R.C.P. Edin., D.P.H. Cantab. Department of Education, Sudan Government, Khartoum. 1904. Pp. 84.

IN 1902 Mr. Henry S. Wellcome generously equipped the Research Laboratories of the Gordon College in the Sudan which were instituted for the purposes of (1) technical education; (2) the study of tropical disorders, especially of the Sudan, of both man and beast; (3) the study of the detection of poisons; (4) the chemical and bacteriological examination of water; and (5) the testing of materials of practical interest in the industrial development of the Sudan. Dr. Andrew Balfour was appointed director and reached Khartoum in January, 1903, and at once set to work to get the laboratories into working order. They now have the nucleus of what will eventually prove to be a most valuable collection of specimens and photographs of human pathology and tropical diseases. A "therapeutic garden" has been started to facilitate the study of the indigenous drugs and poisons of the Sudan. In several instances also medical officers in Khartoum have seized the opportunity of working in the laboratories.

The volume before us embraces the record of the first year's work. Dr. Balfour first describes that taken in reference to mosquitoes. Of the varieties found in Khartoum and its neighbourhood the commonest is *culex fatigans*, responsible for filariasis and dengue. The presence of this mosquito, however, had no very alarming effect. The *pyretophorus costalis*, however, had seriously to be reckoned with as it is both a filaria and a malaria carrier. The *stegomyia fasciata*, the carrier of yellow fever, was also found, as well as some other varieties. To get rid of these pests "mosquito brigades" were formed and the mosquitoes were attacked chiefly in the larval stage. This was comparatively an easy task as there were no swamps or ditches in Khartoum Crude petroleum was employed, about one pint being used for each well. The oil was simply poured down the well and then the water was not disturbed for 48 hours. All unused wells were closed whilst covers were fixed on those in use. The steamers on the Nile were also treated with crude petroleum, in addition to periodical emptying of the bilge water and fumigation with sulphur squibs. As the result of these measures Dr. Balfour estimates that 222,000 mosquitoes were destroyed, so that there has been an enormous depletion of these agents of disease. Another good result of the labours of the "brigades" has been to locate every well in Khartoum, a matter of great importance in the event of any outbreak of cholera or enteric fever.

In the section on Biting and Noxious Insects other than Mosquitoes is detailed a discovery by Lieutenant-Colonel Griffith, D.S.O., who was equipped by the laboratory with a small entomological outfit previously to his journey up the White Nile. This officer brought back specimens of the glossina morsitans caught on the Pongo river in the Bahr-el-Ghazal province. This fly had not previously been reported so far north in these regions. A very interesting portion of the report is devoted to the insects and vegetable parasites injurious to crops. The diseases discovered from an examination of the blood, the fæces, the urine, the sputum, and the skin are next detailed; then those detected by a general examination of the body are described, and, finally, the various local affections are noted. A chapter is devoted to the subject of eosinophilia in bilharzia disease and dracontiasis, and the report concludes with an account of the mosquitoes of Egypt, the Sudan, and Abyssinia by Mr. F. V. Theobald.

Should future reports equal the present one the Egyptian Government must be held fortunate in possessing so able a director of the Khartoum Laboratories as Dr. Balfour. The work shown is also an example of the good seed sown by the London School of Tropical Medicine, from which Dr. Balfour proceeded to Khartoum.

LIBRARY TABLE.

Examination of the Urine: A Manual for Students and Practitioners. By G. A. DE SANTOS SAXE, M.D., Assistant Pathologist to the Columbus Hospital, New York, &c. London, New York, and Philadelphia: W. B. Saunders and Co. 1904. Pp. 391. Price 6*s.* 6*d.* net.—Dr. Saxe's little book on the examination of the urine possesses many commendable features. It is of convenient form and size and is printed in clear type, with headings in dark letters, rendering reference to the different tests easy and rapid. It also gives a very complete account of the subject, dealing not only with substances commonly sought for in the urine, such as albumin, phosphates, chlorides, sugar, uric acid, and so forth, but also with the tests for purins, for kreatin and kreatinin, and for various pigments, rare acids, and bodies occasionally found as curiosities The names of authors who have devised special tests are quoted, but the references to their original articles are not given; we think that the value of the book would have been enhanced by the inclusion of a certain number of such references, especially in the case of methods which have not yet established their claims to acceptance. The information given is generally correct but we notice that the account of Pavy's solution as a test for sugar is very meagre and that the composition of the fluid is inaccurately stated, as the essential constituent, the ammonia, is not included. The latter part of the volume is devoted to the diagnostic import of the urinary findings and to methods of testing the functional activity of the kidneys, such as cryoscopy and injection of methylene blue or phloridzin. The classification of the various forms of nephritis is at present in so confused a condition that any scheme adopted would probably invite criticism. We venture to doubt, however, whether any distinct line can be drawn between some of the toxic conditions here classified as acute congestion of the kidneys and acute nephritis, while the division of chronic nephritis into chronic diffuse and chronic parenchymatous forms seems to rest upon a very slender basis, as is sufficiently indicated by the synonyms given as applicable to the two conditions respectively which appear mutually interchangeable. The book is very fully illustrated and among the figures are some useful illustrations of foreign bodies, such as starch granules, lycopodium, linen fibres, and similar materials, which often cause difficulties to the inexperienced. In view of the American spelling, "chemic" and "spheric" for "chemical" and "spherical," we wonder how it is that "clinical" escapes the docking of its final syllable. Probably the word is too commonly used to be altered; the artificial nature of the new spelling is sufficiently indicated.

The Religion of the Koran. The Wisdom of the East Series. By Arthur N. Wollaston, C.I.E. London: The Orient Press. 1904. Pp. 70. Price 1s. net.—As the sacred volume of some 170,000,000 of the present inhabitants of the world the Koran possesses an interest and an importance which well merit and will amply repay attention and study. It is universally allowed to be written with great elegance and purity of style. It would be difficult to surpass the eloquence and the beauty of the diction. As Mr. Wollaston says, "Well may Muhammad have disclaimed all power of working miracles, trusting to the sacred book as evidence of his mission from on high." In his introduction the author gives an interesting outline of the religion of Islam, and the little book will no doubt be well received as it is full of interest to lovers of Oriental lore. The extracts are sufficiently full to give an adequate idea of the teaching of the Koran.

The Art of Choosing a Husband. By Paolo Mantegazza. Translated from the Italian by Gabriel Claude Charton. London: Gay and Bird. 1904. Pp. 322.—This book contains a father's advice to his daughter on this most momentous question. The father is a medical man and the book is one which all may read and learn much from and yet, good as it is, we hesitate to recommend it for the perusal of young girls. Some of the pages have a continental flavour about them which is not pleasing. Had such portions been omitted in the translation there would have remained an amusing and instructive volume for our daughters. In discussing the professions, the father's advice may thus be summed up: Never marry an idler, a banker, a mediocre author or artist, or a medical man of little culture, who may always be compelled to flounder in mediocrity. In the medical profession the only good seats are in the stalls and boxes; the pit is a prison and the gallery is the penal settlement where hard labour is enforced. Medicine is a profession in which it is impossible to climb to the topmost height unless encouraged by human love or the aspiration for fame. Experience teaches that, everything else being equal, the soldier is the best of all husbands.

The Addison Temperance Reader, with Chapters on Thrift and on Juvenile Smoking. By William Finnemore. London: The Addison Publishing Co. Pp. 219. Price 1s. 6d.—This "Reader" was written by an ex-teacher who for several years was a lecturer on temperance in public elementary schools. The book has been read and revised in proof by several persons of judgment and with special qualifications for such work. It is written in a simple way and in moderate language and therefore commends itself to us, as it may well do to the teachers in our elementary schools. The chapters which bear on the formation of habits will be found particularly valuable. The book is illustrated by diagrams and pictures.

JOURNALS AND MAGAZINES.

The Journal of Anatomy and Physiology, Normal and Pathological, Human and Comparative. Conducted by Sir William Turner, K.C.B., F.R.S., D. J. Cunningham, F.R.S., G. S. Huntington, M.D., A. Macalister, F.R.S., and J. G. M'Kendrick, F.R.S. Vol. XXXIX., Part 2. January, 1905. With plates and figures in the text. London: Charles Griffin. Annual subscription, 21s., post free.—The contents of this number are: 1. Two cases of Fourth Molar Teeth in the Skulls of an Australian Aboriginal and a New Caledonian, by J. T. Wilson, M.B. Edin., Professor of Anatomy, University of Sydney, N.S.W., with two plates. 2. The Development of the Retina in Amphibia; an Embryological and Cytological Study, by John Cameron, M.D. Edin., with two plates. 3. The Relations of the Superior Oblique Muscle of the Eye in the Mammals, by Frank S. Poole, B.A. In this article are contained some novel observations on the angle of divergence of the superior oblique from the middle line in several animals. 4. The Os Calcis, Part ii., by P. P. Laidlaw, B.A., with five plates. 5. The Histology of Lymphatic Glands: the General Structure, the Reticulum, and the Germ Centres, by T. L. Bunting, M.D. Edin. 6. The Theory of Nerve Components, especially with regard to its Relation to the Segmentation of the Vertebrate Head, by Onera A. Merritt, B.Sc. This number contains the Proceedings of the Anatomical Society of Great Britain and Ireland for November, 1904.

The Practitioner.—This magazine makes a good start for the new year. The January number opens with a valuable article upon Moveable Kidney by Sir Frederick Treves who concludes that a very small proportion of the cases of this complaint require operation. A series of articles upon Diet in Pulmonary Consumption are scientific and valuable and the practical conclusions to be drawn from experiment and clinical evidence are excellently set forth in Dr. Arthur C. Latham's capital contribution. Articles on Gastro-enterostomy, on the Parasites of Small-pox, Vaccinia, and Varicella, on Tramps and Small-pox, and several reviews unite to complete an excellent issue.

The Journal of Physiology. Edited by Sir Michael Foster, K.C.B., F.R.S., and J. N. Langley, F.R.S. Vol. XXXII. No. 1. Dec. 30th, 1904. London: C. J. Clay and Sons. Price 6s.—The articles contained in this number are the following: 1. The Lymph Flow from the Pancreas, by F. A. Bainbridge, M.D. Cantab., with two figures in the text. The conclusions at which the author of this article arrives are that the intravenous injection of the substance obtained from the intestine by Mr. W. M. Bayliss and Dr. E. H. Starling and named secretin by them, or of the extract of the ileum, causes an increased flow of lymph from the thoracic duct; that this increase continues after the injection of secretin but not after the injection of the extract of the ileum when the portal lymphatics are ligatured; that secretin itself and not any depressor substance is the active agent in causing the increased flow of lymph; and, lastly, that there is a close relation between the secretion of pancreatic juice and the increased flow of lymph. 2. The Changes in the Viscosity of the Blood produced by Alcohol, by R. Burdon-Opitz, Columbia University, New York. The viscosity values were determined by the time occupied by a measured quantity of blood under a certain pressure in passing through a capillary tube of known size. Alcohol always rendered the blood more viscous, whether introduced into the system by intravenous injection or through the digestive tract. 3. The Gaseous Metabolism of the Kidney, by J. Barcroft, M.A., and T. G. Brodie, M.D. Lond., F.R.S. These experimenters find that the production of diuresis is accompanied by a marked increase in the amount of oxygen absorbed, though the increase is not proportionate to the degree of diuresis. In only one of several experiments was there an increase in the amount of carbon dioxide eliminated during diuresis. The onset of diuresis is not accompanied by a proportionate increase in the flow of blood through the kidney. The experiments were made on dogs. 4. The Relationship of the Thymus to the Sexual Organs; Part ii.: The Influence of Removal of the Thymus on the Growth of the Sexual Organs, by D. Noel Paton. The author finds that there is a reciprocal action between the thymus and the testis, each checking the growth of the other. 5. The Universal Presence of Erepsin in Animal Tissues, by H. M. Vernon, M.D. Oxon. The kidney was found to be richest in erepsin, then the intestinal mucous membrane, and then in succession the pancreas, the spleen, and the liver; the skeletal muscles and the brain were the poorest of all in erepsin. 6. The Formation of Prussic Acid by the Oxidation of Albumins, by R. H. Aders Plimmer, D.Sc. The author finds that by the oxidation of albumins with chromic acid a constant amount of prussic acid is evolved which varies with each albumin; the prussic acid arises from the glycocoll and aspartic acid but the other amido-acids also give rise to a small quantity. 7. The Effects of Adrenalin on Sugar and Nitrogen Excretion in the Urine of Birds, by D. Noel Paton. The author finds that adrenalin when administered subcutaneously causes glycosuria in birds as in mammals and does not act through the pancreas. 8. Some Observations upon the Functions of the Thyroid and Parathyroid Glands, by Swale Vincent, professor of physiology in the University of Manitoba, Canada, and W. A. Jolly, University of Edinburgh. The experiments made by these authors show great diversity of results in different animals. 9. The Selective Action of Cocaine on Nerve Fibres, by W. E. Dixon, M.D. Cantab., with five figures in the text. The author finds that cocaine locally applied picks out and paralyses some fibres before others, as sensory before motor-vagal fibres, fibres conducting upwards before those conducting downwards, vaso-constrictor fibres before vaso-dilators, and he suggests that it might hence be of service in early chloroform narcosis. This number of the journal contains the Proceedings of the Physiological Society for Nov. 12th, 1904.

New Inventions.

ASEPTIC TABLES FOR OPERATIONS AND DRESSINGS.

THE "phosphor bronze" metal with which Messrs. Allen and Hanburys, Limited, of 48, Wigmore-street, London, W., are making articles for use in hospitals and consulting rooms seems to be peculiarly suitable for the purpose by reason of *its great strength, cheapness, and its acid-resisting* and anti-corrosive properties. It takes a high polish but if left untouched assumes in the course of time a dark and pleasing colour somewhat resembling mahogany. We have had our attention drawn to an operation table constructed with this metal the special features of which are a head- or leg-rest (Fig. 1) and an improved means of altering the plane of the table. These improvements possess advantages to the patient as regards comfort and greatly facilitate the work of the surgeon or his assistants in rapidly and with little exertion altering the position of the patient. With regard to the head- and foot-rest racks, screws, and cones are entirely dispensed with and adjustment is made by pressing a handle to the right or the left. The dotted lines show the handle turned to the left. The angle of inclination is fixed automatically, the ends of a moveable rod engaging holes in fixed gun-metal quadrants clearly shown at either side of the table in the illustration. The table itself is placed at any inclination required by means of a lever which is easily worked with one hand. The position is locked automatically, the mechanism which effects this being remarkably simple and for all practical purposes impossible to get out of order. These tables have already been supplied to St. Thomas's Hospital and other hospitals. The aseptic dressing tables are constructed with the patent corner illustrated above (Fig. 2). The plate-glass shelves can be cleaned and dusted without being removed from the framework. The shelves rest on a very small surface, while the duster can be *freely passed around every corner and angle.* The ball-bearing castors attached to these tables are so made that the table moves with a slight touch. It should be mentioned that the operation tables are also fitted with patent castors which, by means of a lever, can be put out of action when required.

FIG. 1.

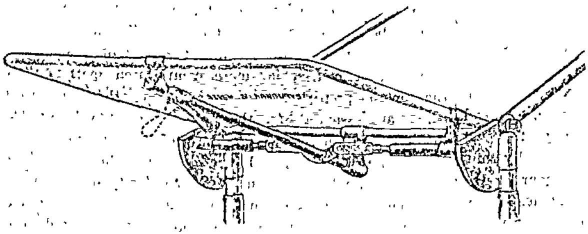

FIG. 2.

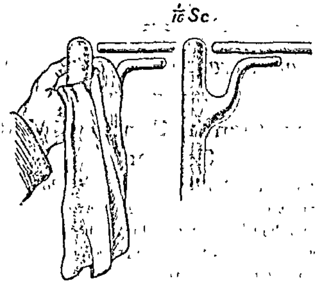
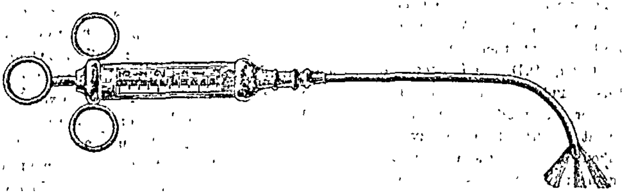


AN INTRALARYNGEAL SYRINGE.

THIS instrument differs from the ordinary intralaryngeal syringe in having three apertures placed laterally instead of one central opening, an arrangement which insures distribution of *the injected fluid over the supraglottic region. It* will be found equally useful for intratracheal injection, since the combined sectional area of the apertures is sufficient for the free escape of the fluid. Messrs. Mayer and Meltzer of 71, Great Portland-street, London, W., have made a most serviceable instrument graduated to a capacity of four drachms.



WYATT WINGRAVE, M.D. Durh.,
Physician, Central London Throat
Devonshire-street, W. and Ear Hospital.

LONDON SCHOOL OF TROPICAL MEDICINE.—Of the students who attended

Dr. J. H. Cook, Mr. D. Alexander (colonial service), Mr. T. G. D. Cooper (colonial service), Dr. D. H. Ainslie, Mr. W. A. Densham, Dr. H. N. H. Joynt (colonial service), Dr. G. H. L. Fitzwilliams, Mr. P. Phillips (colonial service), Dr. J. Gillies, Miss Kathleen Dawson, Dr. D. A. Ashton (colonial service), Dr. J. C. Carr, Mr. R. Dane (colonial service), Mr. J. W. Gromitt (colonial service), Mr. C. H. D. Ralph (colonial service), Mr. A. C. Lorena (colonial service); Dr. F. L. Norris (colonial service); and Dr. W. F. L. A. Holcroft (colonial service).

THE LANCET.

LONDON: SATURDAY, JANUARY 14, 1905.

A Seventeenth Century Medical Sermon.

THE art of preaching has, there is no doubt, declined since the great days of the sixteenth and the seventeenth centuries and the Church can no longer boast an ANDREWES, a BOSSUET, a TAYLOR, or a VIEYRA Even special occasions such as those with which the medical profession is more intimately connected—namely, the meeting of the British Medical Association or the anniversary services of the Guild of St. Luke—but rarely give rise to sermons which have the rhetorical force and the literary power of the old sermons. The old preachers were not afraid to draw startling morals and to use brilliant illustrations to set forth spiritual truths, and their discourses, although nowadays they would be considered forced in interpretation, afford most admirable reading. By the end of the seventeenth century the light was waning and although the mystical interpretation of Scripture was still employed yet the results were that the preacher drew somewhat muddy waters from the wells of knowledge. After ANDREWES and TAYLOR there were but few who could deliver a really moving sermon. A curious specimen, by no means the worst of its class, is now lying before us, being "A Sermon preached at St. Anne, Blackfriars, before the Company of the Apothecaries of London, Septemb. 8th, 1681, and at their Desire made Publick, by ANTHONY WALKER, D.D., and Rector of Fyfield in Essex." To this "Publick" copy of his discourse the Reverend Doctor has prefixed a preface in which he expresses his gratitude that the Company should not have in any way taken offence at the plain way in which he had warned its members of the flies which might find their way into its ointment. He also provides "arms to obviate two possible assaults" from those members of the public who were not apothecaries. "First of those who may grudge at the right and honour I have endeavoured to do your Profession. Secondly of those who may Subsann and expose my Phrase, because I sometimes speak (tho' sparingly) in your Language, and keep close to that Notion."

To come to the sermon itself: the text was taken from Ecclesiastes, chapter ten, the first verse. "Dead flies cause the ointment of the Apothecary to send forth a stinking savour: So doth a little Folly him that is in reputation for Wisdom and Honour." Dr. WALKER commenced by pointing out to his audience how the text sets forth the exceeding nobleness of the profession of apothecary, and, further, that "the most excellent and useful things may be corrupted or perverted by the casual or careless mixture of a little Evil." A fly is but a small thing and only gets into the ointment through carelessness. He then shows that besides the literal flies there are many who are flies in a mystical sense. Such are careless apothecaries who supply bad drugs. Moreover, he directs them: "Remember there are a swarm of Quacks and Empyricks, Mountebanks, Elixorists, Catholicists, as numerous as a swarm of Flies: and one Fly will quickly spy another: These watch your haltings, if you make blots these Gamesters will be sure to hit them: If you give any one a fly to swallow, they will fetch it up again without straining and present it spitefully to the whole City, in the Dimensions of a Camel: Therefore for the Honour of your Profession, and to take away occasion from them, who feel occasion to reproach you, Keep off the Flies. ...... Those little creeping Sneaks who walk like the Pestilence in darkness, under no Protection or Warrant but their own ignorant Presumption, may kill in secret and no man sees them; and their surviving Friends are ashamed to tell who hurt them for fear of blasting their discretion and they should dye unpitied for venturing their lives into such hands; and the Mushroom that did the Mischief hurts no man's credit but his own: which before was lost to all wise men; for it is his pride to stand alone; and his tool is of his own Invention, which no man ever heard of but himself. But you Stand in an Open Light, the beams of Publick Authority shine round about you. ......" For all this he reminds the apothecaries that they had no right to practise medicine. "There is vast difference between making and administering Physick. Nothing is more Common than for one Trade to make Tools for other Trades to work with."[1] Finally, the preacher passes to consider his text tropologically, following out the mediæval distich:—

> "Litera scripta docet · quid credas Allegoria ·
> Quid speres, Anagogo. quid agas Tropologia"

Flies are sins and one sin can and does do infinite harm; his hearers must be zealous and fervent in spirit for "This will keep off the Flies of wanderings, weariness, dulness, coldness: while the Oyntment boils, or keeps its heat, no Flye will light or venture to remain a blowing time upon it. ...... I have treated you from the first part of the text as Citizens *of London and from the second as Citizens of Zion.* ...... *For* although a bad man may be a good Apothecary; a bad Apothecary, a man dishonest in his trade and Profession, cannot be a good Man." So ends this quaint and very telling discourse, one in which there is sound wisdom worthy the consideration of every man who exercises a trade or a profession. The language is homely and the similitudes may be to our hearing farfetched but it never yet did a man any harm to be told boldly of his actual or possible faults.

The treatment of disease and the care of a sick man comprise, of course, far more complicated matters than the mere preparing of drugs. But those qualities which are essential for the professor of the latter are in every way necessary for the professor of the former. Knowledge, diligence, and carefulness are the foundations of the medical profession. The complexity of medicine, by which word we include all branches of the healing art, is so great that no man can be thoroughly acquainted with the whole of it. But if he has built a sure foundation in his student days he can during his professional life raise a superstructure of scientific and practical learning which will enable him to ease many pains, to sweeten perhaps to save, many lives, and to become the trusted friend of many of his fellow creatures. Such a practitioner is not only the man who knows many things but he is fully aware of the limitations of his knowledge. To again quote the old divine: "The higher any man is raised in Reputation, by manifesting himself wise, the more circumspect he is concerned to be to secure his station; for a little Folly will depose him, tho' he reigned over men's minds by the Scepter of his Wisdom. 'Tis ticklish standing on a Pinnacle: and besides the danger of becoming giddy: a small inclining either way may bring him down by the overpoise of his own weight. His height exposes him to all men's view, to most men's envy; and 'tis next to impossible for him to tread awry without severest Censure, who hath so many watchful eyes upon him. ...... The Good Man is the Wise Man and the Sinner is the Fool."

---

[1] Apothecaries were not allowed to practise medicine until the reign of George II.

◆

Sea Voyages for the Treatment of Tuberculosis.

OUR Berlin Correspondent this week alludes to arrangements made by the Hamburg-American Steamship Company to organise a scheme for the treatment of tuberculous cases by sea voyages. This renders particularly interesting a communication that we have received from a Scottish physician stating that it is proposed to attempt a new departure in the treatment of tuberculosis by sea voyages. A large sailing vessel will leave this country about the end of January for a long voyage in warm latitudes and will be prepared to convey a "number of consumptives limited to 50, of inebriates, and of other invalids." It is intended that the patients suffering from tuberculosis shall live on deck day and night whenever the conditions of weather permit, so that they may have the advantage of constantly breathing absolutely pure air containing much ozone. During the voyage the vessel will call at, among other places, Gibraltar, the Canary Islands, Rio de Janeiro, River La Plata, Pernambuco, and the West Indian Islands, and opportunities will be given for the patients to land and to see a little of the countries thus visited. Such is the prospect put before a limited number of invalids whose circumstances, physical and social, permit them to avail themselves of it. And while we must be allowed to point out that there are drawbacks as well as advantages to such a scheme we think that every medical man having a case under his charge which appears fit for such treatment should make further inquiry upon the matter.

The treatment of tuberculosis by means of sea voyages has not been so generally adopted in more recent years as formerly. There are several obvious disadvantages which life on board ship entails, the chief of which are the closeness of the cabins during bad weather and the difficulty of providing fresh meat, vegetables, and milk which are so essential for the welfare of tuberculous patients. On a large sailing vessel the diet can in a great measure be arranged satisfactorily and in the latitudes through which it is proposed to travel fine weather may be expected for a greater part of the trip. But in addition to the difficulties which might arise either from adversity of the elements or monotony of the cuisine it must be remembered that the sanatorium treatment of tuberculosis, as scientifically understood, can hardly be carried out in detail on board ship. The objects of the sanatorium treatment of tuberculosis are to attempt to arrest the activity of the disease, to encourage reparative processes, to bring about compensatory hypertrophy of the sound portions of the lungs, and to sustain the power of the heart. These indications are carried out by rest in the open air during the febrile periods, by a good and varied diet, and by carefully regulated exercise. A quiet life in the open air can certainly be obtained on board ship provided that the elements are kindly disposed. The diet presents some difficulties which, however, may to a great extent be overcome. But when the question of exercise is considered then a drawback to the treatment of tuberculosis by means of a sea voyage becomes apparent. Everyone who has travelled much knows how difficult it is to get adequate exercise on board ship. Theoretically a large amount of exercise may be taken by promenading the deck, but special conditions are required here if the exercise is to be satisfactory, while the pacing up and down speedily becomes monotonous and will only be persevered in by persons of considerable resolution. In the tropics pacing the deck can be undertaken only at certain limited times of the day and every deck is not specially adapted for the purpose. Walking on hilly ground, it is true, is found to be highly beneficial for sustaining the power of the heart and thoroughly aerating the lungs Certainly the sloping deck of a vessel under full sail cannot correctly be called "level ground," and it hardly forms a surface favourable to systematic exercise. The watchfulness that may be required to preserve balance is found fatiguing by persons subject to nausea and we think that all invalids would be liable to the same sensation; while walking on deck is only pleasurable if a fair amount of unimpeded space both in breadth and length is at the disposal of the walker, factors that do not always prevail. In spite, however, of the possible drawbacks that we have indicated we think that the scheme may afford many sick persons a valuable opportunity. The project for obtaining a maximum amount of sunshine and fresh air free from dust may be found highly beneficial in suitable conditions, but we believe that cases of tuberculous affections of the glands and the joints will, as a whole, benefit more than those in which the lungs are affected, though undoubtedly certain individuals suffering from pulmonary tuberculosis may take advantage of this opportunity with benefit to themselves. Cases of advanced disease should, of course, be rejected by those in charge of the administration of the scheme. Those most suitable for the voyage are young adults with limited or quiescent disease. Cases with a hectic type of temperature are best treated on land, as are those of a hæmorrhagic type and those complicated with dyspepsia and diarrhœa. It is also, we think, essential that each intending traveller should be a good sailor and fond of a sea life.

We notice that patients other than tuberculous are also to be taken and an excellent therapeutic prospect is thus opened up, supposing that due care is taken against infection. Cases convalescing from pleurisy, empyema, and slowly resolving pneumonia would be especially suitable for such a voyage in search of renewed health. It is fully recognised that many cases of pleurisy with effusion, apparently idiopathic in origin, are really of a tuberculous nature, and nothing could be more advantageous for recovery than a long sea voyage. Young people, too, with a family history of tuberculosis, especially if they exhibit feeble thoracic expansion, would also gain advantage from such a trip. We trust that it will be found possible to keep careful records of the results obtained in the cases of tuberculosis. It would be of great interest to contrast them with those experienced in the sanatoriums in this country and abroad. One of the chief disadvantages experienced by young adults in the sanatorium treatment is the monotony of the life which is usually enforced. On board a sailing ship there would necessarily be periods when a similar monotony would be experienced in spite of all efforts to render the time as pleasant as possible, but the anticipation of visiting fresh lands and viewing new scenes and the reminiscences of the places already seen would go a long way towards dispelling the despondency engendered by routine and it is this moral effect that such a voyage is intended to have upon alcoholic subjects. We think the scheme a good one and we shall watch its developments and results with considerable interest.

Business Cellars.

AN article in a recent number of the *Manchester City News* comments, under the heading "Life and Work in Our Business Cellars," on the conditions under which many men of business are obliged to carry on their work in Manchester, conditions which, alas, are not found only in the great Lancashire capital. Manchester, like other places, has completely abolished the cellar dwellings which were thought half a century ago to be quite fit habitations for the poor, for in all the great towns of England any large proportion of cellar tenements would be regarded as a reproach to the inhabitants. That thousands of civilised beings should have been condemned to make their miserable homes in underground dungeons, amid damp, gloom, and stagnant air, seems to us incredible nowadays. But, as our contemporary points out, what is rightly considered a thing to be condemned in the case of the poor and for night occupation is allowed unremarked if these underground places are used by day for business purposes. The only difference is that the warehouses are used during the day but not at night, while probably the inhabitants of the old cellar dwellings exactly reversed the process. Of course the revival in the best parts of great cities like London and Manchester of cellar tenements is due to the enormous value of land in the centre of such communities. Land in the business parts of Manchester sells at £100 a square yard, that being not at all an excessive price, and land in London and Liverpool—where a crusade against cellar tenements, as our special correspondent says in his letter this week, is now proceeding—is proportionately costly. Our urban by-laws require a certain proportion between the height of a building and the width of the street, so that we cannot in England emulate the building eccentricities of the American towns. But if we cannot build up we can build down and it seems that many warehouses have been built recently in business centres with double cellars, the bottom one being excavated out of the very bowels of the earth. Goods are stored in them and packers and warehousemen work there all day in artificial light (generally gaslight) and with a limited supply of air—necessarily very impure under the usual conditions as to ventilation, or rather the want of it. This matter was brought before the Manchester Chamber of Commerce a few years since when, though all agreed that the matter was one of urgent public importance, nothing was done to prevent a continuation of the abuse of the ordinary laws of living. And Manchester is only one of many towns where the evil custom of working underground persists. In the streets of London, as in those of Manchester, a whole host of underground tradesmen make their living, callous to the gloom and the gas-poisoned atmosphere. Every cellar in some districts is utilised by restaurants and cafés, where the foul air is made fouler by the fumes of cooking, and terrible is the lot of the cooks, the waiters, and the waitresses whose days are spent—too soon spent—in working for what we call "their living" in such conditions. It is a strongly marked inconsistency for the authorities of any city to be so careful concerning dwelling houses, where the workers spend very little more perhaps than a third of the 24 hours, and yet to allow underground warrens for business occupation, extending in very many cases from early morn till late at night, where the conditions are such as to render healthy living impossible. Those of us who walk London with an observant eye know that much of what has been said about Manchester might be said about the metropolis, while no great cities are free from the abuse. Armies of clerks can be seen now and again working in the great metropolitan offices below the level of the road, while many gratings in the pavements belch forth hot and acrid fumes from restaurant kitchens. Much has been done in London to remedy this state of affairs, but much remains before our practical sanitarians. The remedy is, of course, to spread the business part of our cities over a wider area, to let them grow horizontally instead of up and down by removing the necessity for all business to be done at the centre. It is not accurate to attribute all the evils of centralisation to the landowner with his exactions; the state of things is brought about by the struggle of the public to get to the centre, a desire which seems to animate all the workers in the human hive. It is this impulse to get to the centre that will have to give way before the sanitary impossibilities at which we have hinted, and already there are signs that London is beginning to flow back to its periphery. Suburban values have gone up; if the rents have not fallen in the very heart either of business or fashionable resorts the area just without the nucleus has decidedly given way to the competition of outlying parts. Increased facilities for intercommunication and for bringing the environment into closer touch with the contained city will do the rest. Electric tramways, tube railways, motor omnibuses may all be regarded as indications that decentralisation is taking place. In the first instance their object is readily to convey more persons to the centre, but when such facilities have transformed localities in the environment into thickly populated districts these districts will try in as many ways as possible to be self-sufficing.

Annotations.

"Ne quid nimis."

BLOODLESS SURGERY IN BOND-STREET.

THE quack is always with us, as is well shown by the passage in our "Looking Back" column this week, and while the laws regulating the practice of medicine remain as they are we may safely assume that he always will be. At the present time his position is made a more than usually favourable one from the point of view of his own pocket by the eager collaboration of newspapers intent on sensational paragraphs. The orthodox medical man may not advertise in the lay press but the quack who does ill some of the things that are done well by the orthodox may have his powers trumpeted forth high and low. It is an anomalous position that might have moved the pen of Swift or Rabelais to ridicule. Because a man has never learned to do certain things or received an official guarantee of his ability, therefore he may tell all the world that he can do these things—more, he may reap the foolish world's guineas as fast as they choose to sow them. These observations are suggested by a recent visit to the "bloodless surgeon" whose doings in Bond-street have prompted reporters' ravings in certain daily newspapers of late. We witnessed a remarkable exhibition not so much of Mr. Barker's powers but of what people are willing to endure at the hands of a quack when the same treatment would be pronounced as intolerable cruelty in the hands of the medical man. We may say at once that Mr. Barker appeared to us a hardworking individual believing in himself. He is capable of doing good in certain cases, cases in which medical men upon scientific methods are doing more good. He is capable of doing great harm in other cases and we are in little doubt that he does it. We saw cases of adhesions, of old Pott's disease, of old tuberculous hip disease, and of latent curvature treated, and how much damage was done can only be told when a certain period of time has elapsed. We saw much done with great pain that is in hospitals and private surgeries daily effected painlessly. We saw several cases rejected on the ground that no good could be done and in these cases we saw no fee taken.

THE TEMPLE OF ASKLEPIOS AT EPIDAUROS.

IN a volume of archæological memoirs recently published in honour of M. Perrot there is an essay by M. Cavvadias who has for many years so successfully conducted the excavations at the temple of Asklepios at Epidauros. This essay treats of the cure of diseases at that sanctuary and the conclusions arrived at, if strictly correct, are extremely important in connexion with the history of ancient medicine among the Greeks. Pausanias, the traveller, states that he saw at Epidauros, in, or at the approach to, the Heroon, six stelæ upon which were inscribed the names of patients, the malady of each, and a history of the cure achieved. M. Cavvadias has found four of these, one of them bearing an inscription which originally consisted of about 130 lines of 50 letters each but is now very seriously mutilated and defaced. The point of the memoir written by M. Cavvadias is that this inscription confirms those which he has previously edited by showing that in no case were the cures effected at the Heroon of Epidauros secured by medical treatment. His statement is so emphatic that it will be well to quote it verbatim; he says: "Dans le Sanctuaire d'Esculape à Épidaure on ne pratiquait pas une médecine, ou une thérapeutique proprement dite." He goes on to say that the cures of the sick during the Greek epoch were attributed entirely to the direct intervention of Asklepios. The Heroon was not a place for study in which medical men received a training founded on observation and experiment; it was a "holy place" where the patient himself invoked the deity's protection, hoping not for help from human skill but for divine intervention. This being so, M. Cavvadias argues that it is an error to suppose that in Greek times medicine was practised at the Asklepieia. All the texts referring to medical cures at these temples date only from Roman times. The later classical authors have confounded what took place at these sanctuaries in the Roman period with the practice in the Greek era. Strabo asserts that Hippocrates profited by his studies at the Temple of Asklepios at Cos but M. Cavvadias believes that the inscriptions there were no more scientific than those which he has unearthed at Epidauros and if this were so Hippocrates could not have obtained any useful medical knowledge from them. It was only under the Romans that the hierarchy of the temples availed themselves of medical knowledge, as is shown by the inscription of Apelles found at Epidauros.

CHOLERA IN PERSIA.

A REPORT dated October, 1904, received at the Foreign Office from Mr. J. R. Preece, C.M.G., His Majesty's consul at Ispahan, makes reference to the epidemic of cholera which has been ravaging Persia all through the summer. It travelled to the north through Kermanshah and Hamadan to Kom and thence spread north and south to Tehran and Ispahan, while another course was taken *viâ* the Karun to the head of the Persian Gulf and thence to Shiraz. The two streams of infection met at Komishah, 45 miles south of Ispahan. "It has," continues Mr. Preece, "been somewhat severe in the villages of the Ispahan district, but Ispahan itself was for a long time immune. The late Dr. Tholozan, who was chief physician to Nusruddin Shah and on the staff of the French army and had given a great deal of attention to the incidence of epidemic diseases in the East, told me that from his studies he had deduced the fact that in Persia Ispahan was the last place to be attacked, and when attacked it generally escaped much easier than other places. He imagined that this was due to its central position, height, and the extreme dryness of its climate. It is possible that these may have some influence on the course of an epidemic here, but I think there are other causes which account for the immunity of Ispahan: 1. Ispahan is almost entirely served by wells for drinking water, and although generally there is plenty of water from the Zaenderud running through the various canals, which traverse the town from west to east, yet the well water is preferred. This year, however, the canals have been empty. 2. All the latrines of the place are small and shallow and are not, as in other places, simply wells sunk to a depth of many yards in the ground with four leads radiating from them. These are sealed up when filled and a fresh one dug, as is the custom in all other towns I have known in Persia. As the Persians always use water these deep shafts are full of liquid filth which permeates the subsoil, thus impregnating it throughout with fœtid matter. Periodically the latrines are emptied out and night soil is mixed with dry earth and exposed to the sun for some days and, after being thoroughly disinfected, is used as manure for tilling the fields. The contents of the latrines are sold by the

REBOUND

housewife and this is about the only ready-money transaction which takes place in Ispahan. Thus, while Tehran with a population of some 250,000 people has lost, during this epidemic, something like 25,000, and Shiraz with a population of 45,000 has lost about 5000, Ispahan, with 80,000, has not lost more than 500 at the outside." In addition to the information contained in Mr. Preece's report we learn from other sources that the Persian epidemic is attracting attention in Russia. On Dec. 15th, 1904, at a meeting of the Association of Russian Medical Practitioners, Privat-Docent S. I. Slatogoroff gave a lecture on his experiences in connexion with the epidemic of cholera in Persia. He was the chief of the staff sent out by the Russian Minister of Finance to combat the disease. He said that the cholera made its appearance early in the spring of last year in Persia and was most prevalent in the neighbourhood of Shat-el-Arab where it was a permanent endemic under conditions similar to those existing on the Ganges. After reaching Tehran it spread to the north, threatening Tabriz and Magaru, the sanitary conditions of which were most favourable to the propagation of the disease. Dirty water flowed through the streets and served for drinking purposes. In the streets there were trenches filled with human bodies and excrement. There was no medical assistance at hand except that obtainable from native practitioners. The mortality reached 80 per cent. and more but the Russians succeeded in reducing it to 30 per cent. by means of an extensive administration of stimulants such as camphor and caffeine, together with subcutaneous injection of solutions of table salt. In conclusion Dr. Slatogoroff strongly insisted on preventive inoculation, saying that he inoculated about 1500 persons of whom but 27 (1·9 per cent.) fell ill and four died; whereas of the uninoculated 9·7 per cent. sickened. In Tabriz alone 15,000 persons died in two months and the total for all Persia was 150,000 deaths. He feared for Russia in the coming year and distrusted quarantine.

SUPPURATIVE MYOSITIS DUE TO THE GONOCOCCUS.

IN recent years the possibility of widespread infection of the tissues by the gonococcus producing lesions such as arthritis, pericarditis, endocarditis, and abscesses has been shown. Among the rarest complications of gonorrhœa are affections of muscles which may take the form of myalgia, atrophy, or localised inflammation. In the *Johns Hopkins Hospital Bulletin* for December, 1904, Dr. N. M. Harris and Dr. L. W. Haskell have reported the following case of suppurative myositis due to the gonococcus. A married woman, aged 34 years, was admitted on July 3rd, 1902, to Dr. Osler's ward. She had been married 13 years and had four healthy children. Since the birth of the last child, 11 months before, she had suffered from leucorrhœa and had not menstruated. Four weeks before admission a painful lump of about the size of a hen's egg appeared in the right calf. It subsided, leaving a painful swelling. On examination a tender, boggy swelling of about the size of a hen's egg was found at the junction of the sacral and lumbar regions. It was said to be of three or four months' duration. The right lower limb was held semi-flexed and the calf was much swollen, measuring 34 against 28·5 centimetres on the other side. The calf gave a boggy and fluctuating feeling and was very tender. The patient looked pale, sallow, and rather emaciated. The red corpuscles were 3,648,000, the white were 16,000, and the hæmoglobin was 64 per cent. On the 7th the calf was aspirated with a hypodermic syringe and yielded a small quantity of pus which contained cocci and diplococci staining well and decolourised by Gram's method. Cultures showed that they were gonococci. On the 8th the swelling in the sacral region was incised and drained. It was found to be an abscess extending under the erector spinæ on both sides. There was considerable sloughing of muscles, especially above the attachments to the pelvis. The abscess cavity was swabbed with pure carbolic acid and alcohol and packed with iodoform gauze. The abscess in the calf was also incised. It was under the gastrocnemius and soleus muscles and extended up into the popliteal space and contained one and a half pints of pus. There was considerable sloughing of these muscles and of their tendons. The temperature, which had ranged from normal in the morning to 102° F. in the evening, became normal. The patient was carefully questioned as to symptoms of gonorrhœa but beyond the leucorrhœa no history of them could be obtained. The myositis evidently was not secondary to arthritis or tenosynovitis, for she had never complained of her joints. This case is important because, unlike several of the few cases which have been reported as examples of gonorrhœal myositis, the bacteriological evidence was complete. The recorded cases seem to show that gonorrhœal myositis may be due to toxins absorbed into the blood or, as in this case, to implantation of the gonococci in the muscles and that the inflammation may be of all grades of severity, from an early resolving painful induration to such extensive suppuration and necrosis as that described above.

THE MEDICAL DIRECTORY FOR 1905.

THE 1905 issue of Messrs. J. and A. Churchill's valuable Medical Directory appeared in the last week of the past year. One new subject appears in the useful "Abstract of the Principal Laws affecting the Medical Profession"—namely, "Registration Fees." The total number of names for 1905 is 38,361, an increase of 572 over the total of 1904. Of departmental increase the London list shows 6397 names as against 6328 in 1904, the English provincial list 16,718 as against 16,553, the Welsh list 1236 as against 1207, the Scottish list 3733 as against 3696, and the Irish list 2632 as against 2629. The list of registered practitioners resident abroad contains this year 4448 names as against 4292 last year, and the list of service members 3101 as against 3016. The largest increase is shown in the "too late list" which this year contains 96 names as against nine last year. There is thus an increase in every department of the profession. The Directory is a work which is indispensable to members of the medical profession and of great use to those of many other classes and we congratulate the publishers on its prompt publication.

THE NUISANCE ON THE FORESHORE OF BELFAST LOUGH.

MR. P. C. Cowan, chief engineering inspector to the Irish Local Government Board, and Mr. D. Edgar Flinn, one of its medical inspectors, sat in Belfast on Dec. 14th, 15th, and 16th, 1904, to make inquiry with regard to the petition of the Castlereagh district council praying for a provisional order to form a united district for the purpose of abating a nuisance on the foreshore of Belfast Lough. That a nuisance exists was amply proved by medical and chemical evidence and it is due to the existence of a seaweed, the "ulva latissima,' which feeds on sewage and gives off sulphuretted hydrogen; the nuisance is clearly caused by unpurified sewage being allowed to flow into the lough, those on the sides of Belfast Lough saying it is due entirely to the Belfast sewage while the Belfast council retorts that the townships on each side of the lough contribute their share. No feasible scheme to remedy the nuisance was put forward and it is likely that one of two schemes only will be of any use. The one is to reorganise completely the main drainage scheme of Belfast which is totally unfitted for the present size of the city and to carry the sewage down by means of conduits along each side of the lough, one opening at Blackhead on the north-west and the other at Donaghadee on the south-east of the lough, into each of which the drainage of the boundaries of the lough would empty. In this way the waters of the lough would be kept pure. The other plan is, in addition to the formation of bacteria beds, to purify the crude sewage, to carry out a scheme of reclamation of slob lands on each side of the lough. Banks would be constructed from the Kinnegar to Holywood point on the south-east side and from Greencastle on the other side to a corresponding point opposite; these would form the north-eastern boundaries of the County Down and County Antrim reclamation schemes. Once the banks were completed ample material could easily be provided for the gradual work of filling in and reclamation. The sewage, properly treated, would be largely carried away by the current. No doubt this would be a costly undertaking but it would be final and effective and the reclaimed land would constitute a valuable asset so as to recoup whichever authority—harbour, corporate, or rural—carried it out. All other remedies are only partial and piecemeal and will never rectify the present deplorable condition of an otherwise beautiful lough.

THE DISPLAY OF PHYSICAL INFIRMITY AS AN INCENTIVE TO ALMS-GIVING.

THE exhibition by professional mendicants of the results of injury and of genuine physical conditions of a painful nature as well as the display of pretended mutilation and simulated deformity are familiar to all who read the police reports, as well as to medical men, and the methods of the malingerer were dealt with in detail in THE LANCET of Jan. 7th, p. 45. We may sometimes even wonder that the benevolent public should so readily consent to be imposed upon when they are so frequently warned but there seems to be no limit to the credulity of soft-hearted persons who when face to face with what they believe to be great suffering in others do not pause to consider the effect that their alms-giving may have. They forget that charitable institutions exist for the relief of genuine suffering in the poor and that, on the one hand, their money bestowed in aid of hospitals will do far more effective good than when given directly to an individual, whereas, on the other, indiscriminate giving encourages begging on the part of impostors. The recent case of a pretended paralytic in the City has no doubt called attention to such frauds as his, and to the tricks of other members of the begging fraternity, but such misdirected ingenuity as theirs has been a source of profit for centuries, although from time to time detection has been followed by penalties more or less severe. The following instances are to be found in the late Sir Walter Besant's "London in the Time of the Tudors," and one of them shows that then, as now, the medical profession took an interest in their exposure, although the medical man nowadays can hardly act so vigorously on his own initiative as the surgeon described. If he had had to invoke the aid of the police and to waste time in giving evidence he would very likely have left the "dommerar" in peace. Perhaps the fact that the punishment of the detected impostor has grown milder accounts for his continued existence. Sir Walter Besant writes: "The counterfeit crank was a pretended epileptic. He carried a piece of white soap which he put into his mouth to represent the epileptic foam. Harman draws a lively picture of such a man. He begged about the Temple, his face was covered with blood and his rags with mud and dirt. At noon he repaired to the back of Clement's Inn, where in a lane leading to the fields he renewed the blood on his face from a bladder which he had with him and daubed his jerkin and hose again with mud. A certain printer watched him. In the evening he took a boat and crossed the river. The printer followed him and caused him to be taken up in St. George's Fields as a common beggar. They took him to the constable's house, where they stripped off his rags, showing him to be a healthy and comely man with no sign of any disease; in his pockets they found the sum of 13s. 3½d.; they gave him an old cloak of the constable's, in which he sat by the fire and drank three quarts of beer, after which he threw off the cloak and ran away naked. But they found out where he lived—viz., in a 'pretty house, well stuffed with a fair-joined table and a fair cupboard garnished with pewter.' So they took him to Bridewell where they painted him, first in his disguise and next in his proper attire. Then they whipped him through London and brought him back to Bridewell, where he stayed till they thought fit to let him go. The 'dommerar' pretended to be dumb, he carried a forged licence, and generally pretended to have lost his tongue. One of them was, unluckily for himself, caught by a surgeon who proved that he had a tongue, though he had neatly folded it away somewhere, and as the fellow would not speak the surgeon tortured him till he did. This done they hailed him before the magistrate who administered the usual medicine. The Abram man was one who feigned to have been mad and to have been kept in Bedlam for a term of years."

THE ROYAL SANITARY INSTITUTE.

THE thirty-ninth course of lectures and demonstrations for sanitary officers will begin at the Royal Sanitary Institute, Parkes Museum, Margaret-street, London, W., on Monday, Feb. 13th. The course is divided into two parts, the first consisting of four lectures on elementary physics and chemistry and 21 lectures on hygiene, public health, and the duties of sanitary inspectors. The second part, consisting of seven lectures, will commence on Wednesday, April 12th. The lecturers on elementary chemistry and physics are Dr. E. J. Steegmann, medical officer of health of Heston, Isleworth, and Dr. J. Priestley, medical officer of health of Lambeth. Among the lecturers during the month of March are Dr. G. Newman, medical officer of health of Finsbury, and Dr. H. R. Kenwood, medical officer of health of Stoke Newington, the former taking for his subject, on March 1st, 3rd, and 6th, the duties of a sanitary inspector and the latter dealing with infectious diseases, water, and statistics on March 9th, 10th, 13th, and 15th. Mr. W. Hunting will deliver the opening lecture of Part II. on April 12th, his subject being the signs of health and disease in animals destined for food and tuberculin and other tests; Mr. James King, veterinary inspector of the Metropolitan Cattle Market, will give on April 13th a demonstration on diseased meat; and Dr. E. P. Manby, medical inspector to the Local Government Board, on April 26th, 27th, and 28th will deal with, amongst other things, the preservation and storing of foods, the hygiene of cowsheds and dairies, and the laws and regulations affecting the inspection and sale of foods. In connexion with these lectures a series of inspections and demonstrations will take place from time to time. For example, on Feb. 18th a party will be conducted over the Willesden Parish Infirmary by Mr. A. Saxon Snell; on Feb. 25th the Battersea disinfecting station, mortuary, and shelter will be inspected, the demonstrator being Dr. G. F. McCleary, medical officer of health of Battersea; and Mr. J. R. Leggett will conduct on March 2nd a demonstration of bookkeeping as carried out in a sanitary inspector's office at Islington. On April 19th Mr. R. Glover will superintend an inspection and a demonstration at Messrs. Harrison and Barber's knacker yard, Whitechapel. The fee for the complete course is £3 3s., or for Part I. £2 12s. 6d. and for Part II. £1 1s. The Saxon Snell prize, which is to be awarded by the council of the Royal Sanitary Institute at intervals of three years to encourage improvements in the construction or adaptation of sanitary appliances, is offered for the first time this year. It will consist of £50 and a medal of the institute for the best essay on Domestic Sanitary Appliances, with Suggestions for their Improvement. Particulars of the conditions governing the competition can be obtained from the secretary of the institute.

INSANITARY AREAS IN SOUTHWARK.

THE facts of a case reported in the daily press of Dec. 31st, 1904, in which death was, no doubt, accelerated by insanitary surroundings, give us food for serious reflection. We are so much accustomed to evidences in the way of torn-up roads and torn-down houses, of attempts to enlarge and to improve London generally that we are apt to forget the unseen places where any enlightening efforts on the part of the London County Council are yet far to seek. Such spots, unfortunately, still exist. Nor can we applaud any æsthetic endeavours of the Council in the direction of wide thoroughfares or beautiful buildings or lovely statues so long as overcrowding exists within the area of the Council's jurisdiction or so long as a single death can occur in such circumstances as were investigated by Dr. F. J. Waldo on the occasion to which we are referring. The death took place at King's-court, Borough, which lies in an area known as Erith-place. This area is three acres in extent and holds about 850 persons. It is one of three that were officially scheduled as unhealthy and reported to the London County Council in 1898. Yet for some reason, possibly not unconnected with the unprofitable nature of Erith-place as a building site, while the two other areas received due attention the Erith-place area, the worst of the three, has continued to be neglected. The area includes several cul-de-sacs and a network of narrow courts hemmed in by tall buildings. In Erith-place it is possible to shake hands from house to house across the court. In such a neighbourhood disease is rife and thrives apace. There is no remedy but the destruction of such a spot and the very existence of the area is a reproach to the London County Council. We are glad to notice that a statement was made by one witness at the coroner's inquest to the effect that the area is to be cleared. We agree with the coroner, Dr. Waldo, who was "very glad to hear it."

THE MEDICINE-MEN OF CENTRAL AUSTRALIA.

Messrs. Spencer and Gillen's admirable books on the savages of Central Australia and Queensland are quite as delightful to the social satirist as to the serious anthropologist. It would seem that in their obscure way the hitherto despised and neglected "black fellows" of Australia have for long ages been making game (unconsciously, of course) of much that in Europe is treated with solemnity. Molière himself could not have been more severe upon medical men than are the black Queensland practitioners upon themselves. Their etiquette, which is very elaborate, is conceived in a spirit that would have delighted the author of "Erehwon." For instance, until he is well stricken in years the medicine-man of the Arunta and Kaitish tribes must eschew hot drinks and eat no fat, and the young Warramunga medicine-men must drink very little water and abstain from all native dainties, such as big lizard, native cat, wild dog, and "euro." Messrs. Spencer and Gillen knew of a case in which an elderly practitioner died and the cause of death was at once set down to furtive indulgence in this last-named food. When once they are old and grey-haired Warramunga medicine-men may eat anything and can compel their younger *confrères* to bring them in supplies of the forbidden delicacies. "In fact, the old doctors, and especially the particular man who made him into a medicine-man, can kill a younger one who fails to comply with this rule." Both old and young practitioners, however much they may bully each other behind the scenes, maintain a very firm and consistent attitude towards the public. All disease is set down to the existence in the system of "foreign bodies!" The sick man is always held to have a bone, not necessarily in his leg, but anywhere inside him. The object of the medicine-man is to locate this bone and to point out its wanderings—from the forehead downwards—to an open-mouthed audience. Having done so for some days, he extracts or "exorcises" it and "finds" it at a distance where he has previously buried it. The Anula medicine-men, however, who allow women to practise, are degenerates, or they mark an earlier stage in development, for they do not profess to extract bones but to introduce them below their victims' skins. They are necromancers pure and simple. Strange to say, it is not easy to become a medicine-man. The initiation is long and severe and involves visions, during which the aspirant fancies he exchanges intestines with a tutelary spirit. The power of the medicine-man resides almost entirely in an amulet worn in the nose. This is manufactured by some veteran practitioner out of fur string and is said to be the work of certain very powerful old serpents, reptiles as much connected with medicine among the Australian aboriginals as in ancient Greece.

AMŒBIC DYSENTERY.

AN instructive report has been issued by the Government Laboratory, Manila, on the subject of amœbæ and amœbic dysentery.[1] The first part by Dr. W. E. Musgrave and Mr. M. T. Clegg deals with the cultivation of amœbæ and their etiological significance. On a culture medium consisting of meat extract and agar, rendered alkaline to phenolphthalein to the extent of 1 per cent. and sometimes with the addition of a trace of peptone, it was found possible to cultivate various amœbæ. The amœbæ were isolated by a modified method of plate culture; the material containing the amœbæ is well spread over a sterile plate of the agar medium and an isolated amœba having been located by means of a Zeiss A A objective this is replaced with a clean dry Zeiss D D lens which is then lowered on to the amœba. In many instances the amœba adheres to the lens and may then be transferred to a fresh plate of agar and in this manner a pure cultivation may be obtained. It was, however, found impossible to grow the amœbæ unless bacteria were also present. Various bacteria will serve this purpose, e.g., the spirillum choleræ, but often the amœbæ exhibit a selective action for certain bacteria and without these refuse to grow. All the amœbæ studied developed best at room temperature. With regard to the etiological significance of amœbæ Dr. Musgrave and Mr. Clegg believe that all species are, or may become, pathogenic. In amœbic dysentery the amœbæ can be detected with certainty only when they show their characteristic motility on a warm stage and they are best demonstrated in the fluid portions of the stools after the administration of a saline cathartic. In the second part of the report by Dr. Musgrave the treatment of amœbic dysentery ("intestinal amœbiasis") is dealt with. The various methods of treatment are discussed and a word of warning is given on the use of ipecacuanha which Dr. Musgrave considers may be dangerous in the case of patients much reduced in strength by long continuation of the disease. When bismuth and similar substances are used enemata may be inefficient owing to the bowel being coated with a sticky deposit which should first be cleared away with a saline purgative.

---

[1] No. 18, Bureau of Government Laboratories, Manila, 1904.

Directions are given for the proper use of enemata and cold solutions of quinine salts—1 in 1500 to 1 in 750—are considered to be the best of all. A useful survey of the literature of the subject is given and the report is illustrated with a number of plates.

THE MAKING AND UPKEEP OF ROADS.

AT first sight there would not seem to be much of a medical interest about the above-mentioned subject. But there can be no question that good roads are an important factor in the health of the people, primarily from a sanitary point of view in towns and secondarily in the country because on good roads depends in great measure agricultural prosperity and on this in its turn depends the question of the overcrowding of towns. Anyone who has ever been in France must recognise how far superior in most cases are the main roads of that country to our own. A London macadamised road is a thing to shudder at. Fortunately there are not many of them but such as exist are a disgrace to a civilised community. They are badly laid to begin with and they are never kept up. The London vestry or borough council's idea of the way to lay a macadamised road is as follows. First of all prepare the ground by roughly grubbing up the old road with a "scarificator." Then take large lumps of granite weighing roughly five or six ounces each and dump them on the scarified roadway. Then run a steam roller over them and cover deficiencies with sand. The pieces of granite being much too big to bind act as levers and tilt when any traffic passes, the sand is washed away by the first shower and in a few weeks the road "pockets." It is therefore full of holes which are generally puddles, especially if the road is watered, and contain decomposing dung. No more care is taken and the roadway is left to itself until it gets too bad even for the municipal authority to bear it any longer. Then out come the scarificator, the large lumps of granite, and the sand and the process begins again. If the road were properly laid at first, according to Macadam's instructions and were to be tended by having hollows filled up as they appeared it would last much longer than it does at present and the surface would be good. An evening contemporary has this week published a most interesting article upon the French Department of Ponts et Chaussées, in the charge of which are most of the roads of that country. It is, we suppose, too much to hope that this country will ever have a similar department but the London County Council might at all events organise a department seriously to take in hand the roads of London, with whatever substance they may be paved. As for rural roads, the bicycle and the motor-car have done a good deal to raise their condition but even now it entirely depends upon the frame of mind of the local authorities as to whether a rural road is good or not and many of them seem to consider that "work on the roads" is a fitting method of employing out-of-work unskilled labourers without considering that to keep a road in order requires a good deal of skill. The influence which a well-laid and cleanly roadway has upon the health of town dwellers is so obvious that it need not be insisted upon further.

THE DESTRUCTION OF ORGANIC MATTER IN TOXICOLOGICAL INVESTIGATIONS.

IN the Russian *Gazette of General Hygiene, Forensic and Practical Medicine* Professor A. F. Grigorieff describes a method for the disintegration of organic material in toxicological analysis. The organic matter (intestines and so on) is first dried at from 70° to 80° C. and then pounded in a mortar. Ten grammes are then placed in a retort and submerged in ten times its volume of strong sulphuric acid. The mixture is then carefully heated, all frothing being prevented as far as possible, until the liquid is of a brownish colour. After cooling slightly ten cubic centimetres of fuming nitric acid are added and the liquid is boiled again. Under this treatment the liquid gradually assumes a yellowish colour. After a time another addition of nitric acid is made and the heating is continued. If the liquid does not become clear and of a bright yellow colour more nitric acid is added. At this point another ten grammes of the organic material may be added and the operation as described repeated. More material may be put into the retort, care being taken to keep an excess of sulphuric acid present. The liquid is then vigorously boiled and the oxidation may be considered to be finished when the evaporation of the nitric acid vapours ceases and when, after being cooled, the liquid becomes transparent and colourless. When much fatty matter is present a larger quantity of nitric acid is necessary and it may be freely added at the commencement of the process. The acid liquid is diluted with water and boiled until no more brown vapour issues. The usual chemical reagents such as sulphuretted hydrogen gas may then be applied for the purpose of separating the metals. Professor Grigorieff experimented with small quantities of most of the mineral poisons in organic material in this way and succeeded in detecting their presence even when they occurred in minute quantities. The process recalls that devised by Kjeldahl in which the destruction of organic matter by strong sulphuric acid is effected and at the same time the nitrogenous compounds are converted into ammonia which may be expelled and estimated and thus the quantity of nitrogen in the original material determined.

ELEVATION OF THE HIPS IN THE TREATMENT OF PLACENTA PRÆVIA.

IN the *New York Medical Journal* of Sept. 17th, 1904, Dr. A. King calls attention to a method of treating placenta prævia which does not seem to have been described previously and which from its simplicity and efficacy appears to be valuable in checking of the hæmorrhage by elevation of the hips. He relates the case of a surgeon who saw in consultation a case of placenta prævia. For several hours there had been slight hæmorrhage and pains. The vagina had been packed with iodoform gauze which was saturated with blood. The surgeon removed the pack and found a marginal attachment of the placenta, the os beginning to dilate and the head presenting. The patient was anæsthetised with ether and placed in the lithotomy position at the edge of the bed. The castors were removed from the bedstead and the side to which the patient had been brought was elevated by means of two chairs placed under the legs so that the patient's body formed an angle of 45° with the horizontal. The canal of the pelvis was then easily accessible to manipulation. The action of gravity by preventing loss of blood and the escape of amniotic fluid facilitated turning. The vagina and the cervix were dilated and the membranes were ruptured over one foot which was brought down. The entire delivery of the child took less than five minutes and not an ounce of blood was lost. A practitioner who heard of the case treated another one with the same excellent result. Elevation of the hips suggested itself to the surgeon because he knew of the great saving of blood due to this position in pelvic operations, especially when veins are cut, and that the bleeding in placenta prævia is principally venous. In hysterectomy when using Trendelenburg's position he never closed the abdominal wound without previously lowering the patient to make certain that hæmorrhage would not follow the change of posture, for he had frequently found that blood welled up from some vein, though not a drop escaped when the hips were elevated. It is certainly surprising that the principle of elevation of the bleeding point, which is so well recognised in the treatment of venous hæmorrhage, has been ignored in the treatment of placenta prævia.

WE record in another column the death of Professor Sklifosovski, which has just occurred at Moscow. Professor Sklifosovski, whose scientific position was a very brilliant one, became personally and favourably known to many of his European colleagues during the Twelfth International Medical Congress which was held in Moscow in 1896. Professor Sklifosovski was president of the organising committee of the Congress and to his efforts was largely due the fact that the immense gathering passed off so successfully.

THE medical officer of health of the Cape Colony states that during the week ending Dec. 17th, 1904, no case of plague in human beings was discovered.

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

SECOND NOTICE.[1]

IN our first notice we dealt with what may be termed the epidemiological portion of this report—that is to say, with Appendix A which relates to the etiological investigations carried out by the inspectors of the medical department of the Local Government Board. We now propose to deal with Appendices B and C in which an account is given of the auxiliary investigations which are conducted year by year by bacteriologists and others specially employed under the direction of the medical officer of the Board.

The Pathology and Etiology of Rat Plague and other Infectious Rat Diseases.

The part played by the rat in the diffusion of plague has been variously estimated by different observers. Some attribute to the rat a very large share in the causation of the disease in the human subject, others regard this rodent as exercising quite a minor influence in this direction. Dr. E. E. Klein has set himself to ascertain by means of a carefully conceived series of experiments what is the precise significance of plague in rats and what are the channels by which the disease in rats is conveyed from rat to rat and from rat to man. In discussing the pestis bubonica which occurs naturally in rats Dr. Klein refers to the disease which prevailed among rats at the Cape of Good Hope and which was believed by Dr. A. Edington not to be plague but a form of hæmorrhagic septicæmia, such as swine fever, fowl cholera, and so on. The result of the work carried out by Dr. Klein with material sent to him by Dr. Edington has led the former to the conclusion that the organism in question was that of plague although it presented certain unusual morphological and cultural characteristics.

As regards the method by means of which the plague is spread from rat to rat the experiments of Dr. Klein do not tend to support the view which was put forward by Simond, and which has been strongly supported by others, that the disease is, to any large extent, conveyed from rat to rat by means of fleas. Dr. Klein has been unable to repeat the experiments of Dr. F Tidswell who found that an emulsion of fleas taken from a "plague-dead" rat was capable of conveying plague to other rats. Fleas may, in Dr. Klein's view, occasionally convey plague from rat to rat, but this is not, he thinks, at all a common method of conveyance. After keeping on numerous occasions the rats in the same cage for some time in order that their initial fights might cease one of the animals was inoculated with plague from which it subsequently died, but in no single instance has the healthy rat succumbed to the disease until long subsequently; to test its susceptibility it was inoculated directly and died. Moreover, the rat first inoculated has in numerous instances had opportunity of infecting by means of its fleas the rats kept in adjoining wire cages; but here, again, no such flea-borne transference has ever been observed. In Dr. Klein's view one of the most common causes of infection from rat to rat is by means of the wounds and abrasions which are to be found on nearly all rats in the wild state. Such an abrasion may easily become inoculated by articles soiled by the excreta of rats ill with plague. He thinks, too, that many rats are inoculated owing to their fighting propensities and to the fact that rats ill with plague are extremely irritable. In the case of a rat afflicted with pneumonic plague the oral mucus would be thus a ready means of infection.

But perhaps the most interesting part of Dr. Klein's contribution to the present volume is that which relates to the diseases other than plague from which rats are liable to suffer. It is certainly not improbable that in the past much unnecessary alarm may have been caused by illness among rats which was not due to plague. Dr. Klein refers in the first place to the disease which is caused among rats by the Danysz bacillus by means of which it was sought to destroy the rats in the Paris sewers. There is, however, no difficulty in distinguishing this bacillus from that of plague. In the case, however, of the s.s. *George Royle*, on board of which many dead rats were found while the vessel was being unloaded at Bristol, the case was very materially complicated by the fact that the vessel came from Smyrna which was at that time a plague-infected port. Much alarm was very naturally caused by this circumstance but it was eventually determined by Dr. Klein that the bacillus, which had presumably caused the death of the rats, was not that of plague but a bacillus which he termed bacterium Bristolense. Dr. Klein's communication is of considerable value as indicating caution in arriving at the conclusion that a fatal disease among rats on board ship is of necessity due to plague.

A Bacteriological Test for the Pollution of Air by Saliva.

For many years there has been a growing discontent among teachers of preventive medicine as to the use of the carbonic acid index for estimating the pollution of the air of rooms, factories, and other places. But in the absence of any better standard such test has had to be continued notwithstanding the fact that there are many other sources of this gas than man and animals. Within recent years the Germans, and notably Flügge, have shown with what facility an easily recognisable organism, such as bacillus prodigiosus, can be conveyed through the air by acts of loud talking, coughing, and especially sneezing, and they have also shown by the aid of carefully arranged Petri dishes that during acts of coughing and sneezing persons suffering from advanced pulmonary tuberculosis may disperse the tubercle bacillus for considerable distances both before and behind the seat which they occupy. It is important, however, to observe that in ordinary quiet speaking or breathing few, if any, organisms are given off by the breath. But both these series of experiments related to organisms which may be regarded as abnormal or extraneous in so far as the healthy human being is concerned, and hence Dr. Mervyn H. Gordon has been led to undertake an investigation "to determine whether it is possible to find a bacteriological test of the pollution of air by material given off by the human body comparable to the B. coli (&c.) test for the pollution of water by material derived from a like host; a test capable of application as an index of the possible access of morbific virus to air, in a manner similar to that in which the B. coli (&c.) test is an index of its possible access to water."

After a careful examination of the salivas of a large number of people of different ages and sex Dr. Gordon found, as might perhaps have been expected from the work of Miller, David, and Goadby upon the micro-organisms of the mouth, that the organism which was most abundantly present in the saliva was the streptococcus brevis (Lingelsheim) which Goadby found "in all mouths, healthy or unhealthy, clean or dirty." This streptococcus is in no sense confined to the mouth of man but it is found also in the mouths of monkeys, dogs, rabbits, or guinea-pigs. Dr. Gordon found this organism to be present in great abundance in the several salivas tested by him. It was generally present to the extent of 10,000,000 per cubic centimetre of saliva and sometimes the figure reached ten times that amount. Other streptococci were found, but Dr. Gordon has selected streptococcus brevis as being that which affords the most useful test for the presence of saliva Often, therefore, confirming the experiments of others with bacillus prodigiosus and bacillus tuberculosis, he undertook similar experiments in reference to what may be called the normal flora of the human mouth, that is to say, he engaged different persons to speak for certain periods and with varying degrees of vehemence, and by employing tests on the same principles as were employed in dealing with what we will call the extraneous organisms he found that the normal micro organisms of the mouth were carried by droplets in practically the same manner as Flugge and others have demonstrated to be the case with organisms purposely introduced into the mouth or which were there present by virtue of the diseased condition of the patient Whatever organism was employed it was found that the maximum distance at which it could be detected was 40 feet in front of, and 12 feet behind the operator We have no space to describe in detail the methods employed by Dr Gordon but it must be mentioned that he found neutral red broth the best medium for cultivation by virtue of the fact that its colour is markedly changed by streptococcus brevis when incubated anaerobically for 48 hours at 37° C , a phenomenon which does not ensue in the case of the other streptococci of human saliva As a result of this experience Dr Gordon is inclined to regard the streptococcus brevis test as "almost if not quite as delicate a test for saliva as is B coli for the presence of fæcal matter

---

[1] The first notice appeared in THE LANCET of Dec. 3rd, 1904, p. 1609.

It would seem, therefore, that we may have in the presence or relative abundance of the streptococcus brevis in rooms occupied, or which have been recently occupied by man or animals an indication of the adequacy or insufficiency of the ventilation of the room, factory, or cowshed but the conclusions will naturally be governed very materially by the
xcitement
nce, if the
a factory
wherein strict silence was enjoined we can imagine that the ventilation might be regarded as excellent and a similar remark might be made with respect to a crowded church wherein, or at a time when, the members of the congregation were taking little active part in the service Conversely in a factory where there was much loud talking, in a place of worship when a revivalist meeting was being held, or at times in the London Stock Exchange or Paris Bourse the conditions might be regarded by the streptococcus brevis test as calling for action under the Public Health Act In a public place such as the House of Commons a different standard of *relative abundance* would be necessary, on the one hand during the dinner hour and, on the other, during an altercation below the gangway But, as Dr Gordon observes in summing up his most interesting paper, "the value of the streptococcus test as a means of estimating pollution of air by breath borne material and as a test for the efficiency of ventilation is a matter for the future to determine" He suggests the
draught by way of diverting
any pathogenic organisms wl
mouth of the speaker to some exhaust chamber below the floor We should much like to see this suggestion acted upon and some experiments undertaken with the view of determining the force necessary to divert the droplets given off during a paroxysm of coughing or during some violent declamatory effort

It is, of course, difficult to ascertain to what extent the strepto
ubtless active in
of normal saliva
virulence for the
mouse cannot be regarded as conclusive of their harmlessness in all circumstances It would seem to be clear from the experiments of the Germans conducted some time ago that wherever violent speaking is taking place the hearers in the vicinity are liable to become infected by any infectious disease or condition from which the speaker is suffering, assuming that such infection can be given off by the medium of the saliva, and what Dr Gordon s work has possibly done is amongst other things, to hold out a hope that in the future we may be able to ascertain a means of diminishing this obvious risk without undue interference with our comfort Although a great deal of additional work will be necessary before the carbon dioxide test can be usefully superseded by the one here under discussion the bacteriological test might in certain cases be employed in conjunction with the chemical

A FRENCH SANATORIUM FOR CURABLE CONSUMPTIVES

(FROM A SPECIAL CORRESPONDENT)

AN account of a visit to the new sanatorium for poor consumptive patients at Bligny, 22 miles south west of Paris, may be of interest in the present state of the campaign against tubercle Half an hour in the train to Orsay and one and a quarter hours in a ramshackle country omnibus through quiet domestic scenery bring the traveller to the front gate and without any introduction a medical visitor is warmly welcomed as a *confrere* by the medical director of the institution, Dr Guinard

The Bligny Sanatorium, opened in October, 1903, was erected on the initiation of M Paul Mirabaud, a generous Parisian banker, for the sum of £48,000, and is maintained to a large extent by receipts from patients, assisted by contributions from the charitable society, L'Œuvre des Sanatoriums Populaires de Paris, which erected it The inmates pay £4 a month or if their means will afford it £6 Most pay only £4 Their proportionate cost works out at £5 a head a month The founder was fortunate in his architect M Magne Professeur à l École des Beaux Arts, whose work is as satisfactory to the artistic sense as to the demands of modern science Built in massive style and of good proportions in rough cobble like concrete blocks, which give the effect of old stone and are said to be equally durable, it has from the entrance or side, the general air of an old château adapted to its present use On the reverse aspect, however, there is no question of new wine in old bottles Two heavy wings 120 feet long flank at an obtuse angle the central two floored building of similar length, its face entirely occupied by the galleries which open along their whole length and height, are the essential elements in the treatment Ascending a few steps or passing up the stairway to one or other of these galleries, the visitor looks down a long vista of full length wicker chairs, each separated from its neighbour by a little table on the floor and an electric light on the wall each occupied by the particular one of the 120 inmates who has been assigned to it as he has been assigned to his bed, bedroom, place at table, his distinguishing number, and his general equipment by the director on admission The patients look warmly covered, dressed in a variety of ordinary apparel lying on a thick grey blanket and a couple of cushion pillows, with another blanket to cover them At intervals the line is broken by a glass screen to break up the draught , underfoot is the concrete floor with rounded corners , overhead the beams of the roof and out over the light iron railing a splendid view south south west—the approved aspect—through the park which slopes away into the valley below to the cosy little village of Bris sous Forges to the richly cultivated and wooded undulating country beyond and to the dim blue hills in the far distance An hour later some of the patients are in occupation of the croquet court and bowling ground, others are wandering about the bushes and copses of the 220 acre park, and a few by special leave are walking outside up to a radius of half a mile from the house

The object of this sanatorium is to cure poor male consumptives For this purpose none but cases in an early stage are admitted , the patients do the housework themselves , there are no nurses , and the staff for 120 patients consists only of three medical men a few persons engaged in the offices grounds, and engine house, and a body of 13 women belonging to a religious sisterhood who manage the kitchen linen store, and laundry Having fewer resources than many of us for enjoying idle hours the patients object less than most persons probably would to the very rigid arrangement of their day The printed time table announces that the patient rises at 7 A M , takes his coffee at 7 30 and his douche at the medical attendant s hands at 8 , he then takes his walk till 9 15 , lies down till 10 15 , and eats again at 10 30 , he walks rests eats, rests eats, walks rests, eats and finally rests, till at 9 he goes to bed, and at 9 30 is in the dark The discipline is strict We sat down together to dinner at 1 o clock and to a collation of bread and butter and hot milk at 4 o clock , and we rose again at a signal from the medical man presiding at the table with a great clatter of chairs on the concrete floor as if we were at school. The food was excellent both in quality and cooking; our own poor people would call it luxury if they had the French taste—two meat courses, two vegetables, a soup, and a dessert with a flask of red wine. But forced feeding is not attempted; the appetite only is forced and that only by natural means. Serving at meals is done by the healthiest patients in turn, ten or 12 being detailed for the purpose each day. The bedrooms are similarly tended; the beds are made and all clothes and boots are brushed by the patients themselves. Clothes and boots are brushed in separate cloak-rooms where the boots are always exchanged for slippers on entrance after a walk, prevention of dust and waste matter being considered more effective than accumulation and removal. The bedrooms, containing two or three beds in each, are small but unencumbered by furniture of any kind, with windows which are kept open by a patent lock, being shut only for half an hour before bedtime and in the rare event of a storm driving straight into the room. The patients are unable to close them but they can be closed if necessary. Two or three patients were keeping their beds by order and one was allowed to receive a visitor. In such cases it is obvious that windowless windows are a drawback. All washings take place in the lavatory attached to each bedroom, kept with scrupulous care, or in the douche room in the basement. The douche is a wave, not a spray, and begins at a temperature of 30° C., declining to 12°.

On the ground floor of one wing, passing on account of the slope of the hill into the basement of the central block, are the kitchens, linen store, douche, bottle-washing, dispensary, and medical rooms. The bottle-washing room is of especial interest. Every patient has his numbered pigeon-hole and a couple of pocket spittoons, "crachoirs de poche," flat two-ounce bottles of blue glass with a rubber-lined metal cap which screws on to the neck. One of these the patient keeps always in his pocket, so that no spittoons are seen anywhere about the premises and there is no need for infecting handkerchiefs with tuberculous sputum. When the bottle is nearly full the patient takes it to the bottle-washing room which opens directly both to the outside, and to the passage, and exchanges it for the clean bottle. The bottles are cleaned by an assistant. The sputum is mixed with dry sawdust and burnt. A specially devised, jacketed metal sink receives the bottles, steam is turned on, and the whole is kept boiling, caps, rubber lining and all, for thirty minutes. They are then stood on a wooden stack to dry and when dry are returned to the pigeon-holes. All rags, papers, and soiled materials are thrown into covered metal bins also to be burnt. The medical rooms are of considerable interest. The most important medical instrument of all—the scales—takes a prominent place; and by its side are various strange versions of Laennec's original stethoscope. There are a complete skiagraphic installation with a good developing room which is little used, although there are already a few good skiagrams of caseous lungs to be seen; a high-frequency equipment; apparatus for testing the lung capacity, shape of the chest, and variations of the pulse; and all requisites for bacteriological work, section cutting, and examination of the blood. Some of this outfit, all of the first quality and carefully selected, may at first appear superfluous. But the three medical officers—Dr. Guinard, Dr. Bertelon, and Dr. Dieuzaide—are experts and enter into the details of their special subject with all the single-minded enthusiasm which distinguishes Frenchmen and Germans from ourselves who, as a rule, prefer general knowledge to special. Far from time hanging heavy on their hands it was evident that they take little leisure from their work and seldom go into Paris. All three of them study every single case and study with them is no light task. Besides the usual methods of examination the most detailed microscopic and bacteriological investigation of sputum, blood, and urine is carried out. This is repeated for each patient once in every three weeks and six or seven complete "analytic essays" have therefore to be made out every day. The mass of detail thus collected is made easily available by being entered on a comprehensive sheet of printed questions in which all useful information is properly classified and arranged. Thus the space headed "Personal Antecedents" includes the following sub-headings: growth, habitual health, military service, style of life (*genre d'existence*), antihygienic work, privations, overwork, excess, alcoholism, tobacco, promiscuity, and particular circumstances, besides the more usual details. In examination of the sputum other bacteria besides the bacillus tuberculosis, elastic fibres, and cellular elements are expressly described; in that of the urine cryoscopy and the diazo reaction; and in that of the blood the agglutinating power.

As to therapeutics, little is done beyond giving the most minute attention to general health. Drugs are given only for symptomatic treatment. Local lesions are treated in the usual way. A surgical table and instruments in a glass case have not yet been used but admirable electric laryngeal and nasal lamps and cauteries are in common use, worked from a switchboard at the physician's hand. Dry-cupping is in favour. One man on the day of my visit was sitting in a chair with 20 glass cups of the usual size on his back.

There are two outhouses. In one is the laundry, devised with proper attention to the special requirements of infected clothes, equipped with the most efficient washing churns and centrifugal driers, propelled by water-power, and with a Geneste-Herscher disinfecting apparatus running through a wall between two adjacent rooms. In the other is a double gas-engine which works the electric light and pumps up the water. Drinking water is filtered in Pasteur-Chamberland apparatus. The sewage is disposed of by being water-carried into hermetically sealed iron chambers in the basement, from which it is removed in carts mixed with disinfectant, and, I think, buried at a distance. There is room here for improvements which are being undertaken. The park includes a kitchen garden in which a few of the stronger patients are occasionally encouraged to do some light work. There is at present no satisfactory means of transport between the sanatorium and the nearest railway station.

In all, this establishment at Bligny would seem to leave little, if anything, to be desired and its scope of usefulness is soon to be doubled by the erection in the grounds of a similar sanatorium for 120 women. But it is difficult to keep many patients in the institution for much over the three months to which they are held hostage by the amount of their washing bill and even in the first year's working there have already been several relapses after discharge and not a few intractable cases even in the very favourable group selected for the treatment. It is more useful as a school for consumptives than as a hospital. Would it not be still more useful, as Dr. Newsholme and others have long insisted, if looked on only as a school, giving at the same time a good opportunity for accurate diagnosis, dismissing all idea of hospital functions, and limiting the term of education to a fortnight?

MEDICINE AND THE LAW.

The Law Relating to Medical Practitioners in America.

SEEING that the laws now in force in the United States are to a large extent founded upon English jurisprudence it is not unprofitable to consider the reports of cases heard in the American courts. The decisions of American judges are not, of course, in any sense binding upon an English court of law, but in so far as the judgment of an American court is based upon principle it is at least entitled to respect if cited to an English judge. It should be remembered, however, that in some states of the Union Acts have been passed which have no parallel in this country—as, for instance, the Act which is in force in some States (e.g., New York) which prevents a medical man disclosing the secrets of the consulting room even in the witness-box. In the recently published "General Digest of American Cases" there are some decisions of interest to medical practitioners in England. It is proposed to give an account of some of these decisions in the somewhat peculiar language which appears to be used by the American law reporters. Actions for malpractice appear to be of frequent occurrence in America, if it is fair to judge from their constant appearance in the law reports. The question constantly arises as to what degree of negligence will render the practitioner liable to an action for damages. A physician who is merely a general practitioner cannot be held liable in damages to a patient for diagnosing and treating a disease of the eye as conjunctivitis when it was in fact glaucoma, when the evidence showed that glaucoma is a very rare disease, that it is incurable in character, that its certain diagnosis could be made only by a skilled expert of special training and experience and that it should be treated with remedies and appliances which are never expected to be within reach of the general practitioner of medicine, that its prominent symptoms were so nearly identical with those of conjunctivitis that the diagnosis made by the defendant was one reasonably to be expected from a general practitioner, and that the treatment given was not found faulty by any [illegible] who testified in the case (Wo[illegible] Ct. 213). If a charge of negl[illegible] that the plaintiff must be in a position to substantiate the charge. Thus the burden of proof on the plaintiff is to show that the defendant did not exercise reasonable care, skill, and diligence. In the case of De Long *v.* Delaney, which was heard in Pennsylvania, an action was brought against a physician for failing to use a tourniquet after an accident. There was no evidence from any witness competent to express an opinion that a tourniquet should have been used or that the tight bandage which had, in fact, been used by the defendant was not fully as good. It was held that in the circumstances the judge was right to withdraw the case from the jury. In the case of English *v.* Free (55 A. 777) it was decided that in an action for malpractice against a surgeon evidence that he made an error in diagnosis is insufficient. Some interesting American cases are also recorded in which questions have arisen with regard to fees. Where no fee has been arranged beforehand it is for the jury to say what remuneration shall be paid to the physician for his services and it is often a matter of difficulty to state the criterion according to which the jury must decide the question. In the case of McKnight *v.* Detroit (97 N.W. 772) an action was brought by a physician of high standing for "compensation"—i.e., for fees. The judge told the jury that they should consider the skill and experience of the physician and the character of the services and limit the plaintiff's claim to such sum as would compensate the plaintiff for those services. He would not say that if the defendant was liable at all it was only in a fair and reasonable amount. He also refused to tell the jury that the plaintiff had no right to fix an arbitrary fee and that no number of physicians could agree on a fee to be charged and that it did not make any difference how many patients the plaintiff attended. These matters were to be taken into consideration. It was held in a superior court that this charge was correct. Disputes sometimes arise as to how much is agreed upon to be paid for an operation. In the case of Abram Bros. *v.* Krakower (84 N.Y.S. 529) the plaintiff testified that it was agreed that he should perform an operation for the defendant. Another surgeon was to be present and to receive $500, while the plaintiff was to receive $250. The other surgeon was called as a witness and proved that he attended and received a cheque for $500. The patient (who defended the suit) alleged that the contract was that the plaintiff was the only person to be paid and that he was to receive $750 if a certain operation proved necessary and only $250 if merely the operation actually performed proved necessary. He also alleged that the cheque for $500 had been made payable to the [illegible]

[illegible] that a husband resists a claim for services rendered to his wife. In McCoy *v.* Fletcher (85 N.Y.S. 1022) a surgeon brought an action against a husband to recover fees for an operation performed on the wife. It was proved that the operation was performed with the husband's knowledge. The jury, nevertheless, found for the husband. On appeal, judgment was entered for the plaintiff on the ground that the verdict was against the weight of evidence. It is now a matter of common knowledge that in many States of the Union Acts have been passed which prohibit a physician from disclosing professional information acquired from a patient. Divers questions have arisen as to the effect of this rule. In one case (Crago *v.* City of Cedar Rapids, 98 N.W. 354) it was decided that the expert testimony of a physician, based upon hypothetical questions, as to the cause of an injury to a person whom he had attended as a patient cannot be rejected under Section 4608 of the Code of Iowa, which provides that no physician shall be [illegible]

with [illegible] disclo[illegible] tion [illegible]

prohibited from giving such evidence (Deutschmann *v.* Third Ave. Ry. Co., 84 N.Y.S. 887). Nevertheless, in an action on a policy issued by a benefit society which was defended on the ground of false statements in the application, the testimony of a physician as to the physical condition of the deceased when he was treated by the witness was excluded; but the exclusion only extended to the time of treatment (Dubcich *v.* G. L., 74 P. 832).

The Duties of the Police.

At a recent inquest at Hackney it was shown that the deceased, a plasterer, after a drinking bout had suffered from delirium tremens and in this condition had attacked his wife and children first with a saw and afterwards with a chopper. After a violent and prolonged struggle he had appeared to fall asleep and was left by his terrified family on the bed where he was afterwards found to be dead. The medical evidence was to the effect that death was due to heart failure following upon an attack of delirium tremens and upon the struggle which had taken place. Fortunately, no other death than that of the man himself was the result of the incident, a fact which was in no way due to any assistance received by his unfortunate wife and offspring from the police. They had sent a neighbour for assistance and two constables had actually arrived but had refused to enter the house. As many are [illegible]

was asked for by the coroner's jury as to the conduct of the policemen in the case referred to above and it is to be hoped that the Chief Commissioner has had his attention called to the matter. Every Englishman likes to regard his house as his castle but he does not push this to the point of preferring to be murdered or wounded in it to enduring the intrusion of the [illegible] existing for the [illegible] crime, and will be [illegible] an act of trespass if it is honestly undertaken in the belief that a dangerous act is being committed and can be stopped.

Looking Back.

FROM

THE LANCET, *SATURDAY,* Jan. 13, 1827.

Medical Police, and Secret Remedies.

M. DOUBLE read before the Royal Academy of Medicine of Paris, the first part of a work which he had undertaken in order to prove,—1st. That for several centuries, by the vigilance of the administration, in concert with the most distinguished medical men, the strongest efforts have been made to rid society of the pestilence constantly springing [illegible] to be tolerated.*

In France, the first decree relative to this object was issued by Philip IV., called the *Bel*, in 1311; it prohibited the exercise of the healing art to all those who had not been recognised by sworn masters (maitres jurés) capable of practising the art. Louis XIV., especially by his declaration of 1696 and 1702, and the decree of 1767, manifested a sincere wish to repress the abuses which had introduced themselves into the exercise of medicine. He prohibited to every person, not provided with a valid title, the practice of medicine as well as the sale or gratuitous distribution of medicaments, and included in this prohibition the religious orders. Louis XV. [illegible] the purpose of exa[illegible] inspecting the miner[illegible] The unfortunate Lo[illegible] the Royal Society [illegible] same powers.

The decree of the 10th of August, 1810 may be considered as the resumé of preceding legislation on the subject, and it positively establishes, that *secret remedies ought no longer, and could no longer, be tolerated.*

---

* M. Double's observations cannot apply to England, for quack medicines and quacks abound, and will continue to abound, as long as our government encourages the sale of the one and the constituted medical authorities possess no power to prevent the existence of the other.—ED. L.

THE LANCET RELIEF FUND.

Almoners.

THIS Fund, which came into operation on the 1st of February, 1889, has for its Almoners the President of the Royal College of Physicians of London (Sir WILLIAM SELBY CHURCH, Bart., K.C.B., M.D. Oxon.), the President of the Royal College of Surgeons of England (Mr. JOHN TWEEDY), the President of the General Medical Council (Dr. DONALD MACALISTER, M.A., B.Sc., F.R.C.P.Lond.), Mr. THOMAS WAKLEY, F.R.C.S.Eng., and Mr. THOMAS WAKLEY, jun., L.R.C.P. Lond., with Sir HENRY PITMAN, M.D. Cantab., F.R.C.P. Lond., as Honorary Auditor.

Scope of the Fund.

FOR the guidance of those seeking assistance and of those desirous of recommending deserving cases, it may be useful to record that THE LANCET Relief Fund is sustained solely by the Proprietors of THE LANCET, who provide every January the sum of at least £300, which is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners, or to their widows and orphans, in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require. In the case of widows and orphans, in order to come within the scope of the Fund, the death of the Husband or Father must have been of recent occurrence.

Chronic Cases ineligible.

WHEN the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established, and, as a result, the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. As the Almoners still receive applications for assistance for cases which are obviously of a *chronic* character, it is thought advisable to append a statement concerning cases of this nature which appeared in THE LANCET of Feb. 16th, 1889:—

> "We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registered medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected emergency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief"—

And who, it may be again pointed out, are likely to be permanently benefited thereby.

SIXTEENTH ANNUAL REPORT of the ALMONERS.

For the year ending December 31, 1904.

IN presenting their Sixteenth Annual Report the Almoners have to record that the balance in hand on Dec. 31st, 1903, was £160 2*s.* 3*d.*, to which, on Jan. 1st, 1904, the Proprietors of THE LANCET added the sum of £300, making a total sum of £460 2*s.* 3*d.* available for grants during the year 1904.

The number of applications for assistance received by the Almoners during the year was 55—a decrease as compared with those received in the previous year—of which 15 were so obviously outside the scope of the Fund that they were rejected by the Secretary by virtue of the discretionary power conferred upon him by the Almoners at their meeting on Jan. 1st, 1890; seven were rejected by the Almoners after due consideration; four were withdrawn by the applicants; in seven cases Forms of Application were sent but were not returned—probably the applicants recognised that their cases were outside the scope of the Fund; and 22 applicants were relieved by gifts or loans of money ranging from £5 to £25. The relief of the 22 cases, a detailed list of which is given in the accompanying Statement of Accounts, involved the expenditure of the sum of £266—a sum just within the normal income of the year, omitting balances brought forward and possible receipts from repayment of loans.

Letters continue to be received by the Almoners from some of those whom they have helped, expressing their gratitude for the relief which has enabled them to mitigate, and in not a few cases to overcome, their difficulties, and thus testifying to a pleasing feature in the administration of the Fund.

The promptness of the relief afforded to applicants is also a feature to which the Almoners continue to give their particular attention; in this connexion it may not be uninteresting to record the fact that on several occasions the Almoners have again been able to consider cases and to grant relief on the actual day on which the application was received. In one case of urgent distress (No. 629) the circumstances were considered by the Almoners and aid was rendered within four hours of the application being made.

There continue to be far too many applications received for assistance for what are obviously "chronic" cases, a large proportion of the cases rejected by the Almoners and the 15 cases rejected by the Secretary coming under this heading. It cannot be too emphatically reiterated that THE LANCET Relief Fund exists to meet cases of *sudden emergency*, where timely help will tide the practitioner over unforeseen difficulties, or to afford a widow and orphans a few weeks' respite from the more pressing financial cares of their unhappy position.

The Almoners, in their Report for the year 1901, had occasion to deplore the neglect on the part of applicants who had received loans from the Fund to fulfil their obligations and to repay the amounts of their loans. They have pleasure, therefore, in recording that the sum of £31 was repaid during the year under review.

Dr. Donald MacAlister, M.D., F.R.C.P.Lond., M.A., B.Sc., having succeeded Sir William Turner, K.C.B., M.B.Lond., F.R.C.S.Eng. & Edin., F.R.S., as President of the General Medical Council at the conclusion of the last autumn session, thereupon became an Almoner of the Fund and kindly consented to act as such. Sir William Turner's signature is appended to this Report, he having acted as an Almoner for practically the whole of the period covered by it. The present Almoners desire to record their appreciation of his services to the Fund during six years and of the excellent advice which he was ever ready to give.

In conclusion, the Almoners desire to state that they will at all times be glad to have their attention called to any cases of genuine distress coming within the scope of the Fund but they trust that those recommending cases or giving testimonials will first take steps to satisfy themselves of the *bona fides* of such cases before endorsing them. In the administration of such a Fund as this the Almoners are of necessity largely guided in their decisions by the testimonials accompanying the applications.

Balance at Bank, Dec. 31, 1904 ...				225	2	3
				£491	2	3

I find by the Bankers' Book that the actual Balance on Jan. 1st, 1904, to the credit of the Fund was £160 2*s.* 3*d.*, to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 1st, 1904.

The balance at the Bank on Dec. 31st, 1904, was the sum of £225 2*s.* 3*d.* I have also checked the receipts for disbursements and find the above account strictly accurate.

January 3rd, 1905.

HENRY A. PITMAN, Hon. Auditor.

ASYLUM REPORTS.

London County Asylum, Bexley Heath (Report for the year ending March 31st, 1904).—The average number of patients resident during the year was 2085, comprising 1012 males and 1073 females. The admissions during the year amounted to 585—viz., 282 males and 303 females. Of these, 528 were first admissions. Dr. T. E. K. Stansfield, the medical superintendent, states in his report that "the hopeless character as to the possibility of recovery of the bulk of the admissions during the year is clearly demonstrated. ...... The axiom the sooner the disease can be brought under treatment the greater hope there is of recovery applies more to mental alienation perhaps than to any other form of disease." Only 30 per cent. of cases came under treatment within three months of the beginning of the attack, owing to which, adds Dr. Stansfield, "not only is the possibility of recovery greatly diminished but when recovery does take place the permanent injury present in every case is proportionately greater. The importance of *habit* in relation to mental diseases is but little appreciated and yet to my mind it is one of the most powerful factors in the development of chronic insanity and it remains after the first causes have passed away, as is well illustrated by the bulk of cases in every asylum. All this points to the urgent necessity of patients being bought under proper observation and treatment at the earliest period of their alienation before insane habits of thought and action become fixed." Melancholia was present in 23 per cent., paranoia and delusional insanity in 14 per cent., primary dementia in 13·5 per cent., and general paralysis in 6 per cent of the admissions. Among the causes of insanity were arteriosclerosis, senile decay, alcoholic intemperance, insane parentage, and syphilis, in descending order of frequency. "The important part played by heredity in the causation of mental disease was demonstrated by the fact that insane heredity was made out in 132 cases or 22·5 per cent." The number of cases discharged as recovered during the year amounted to 162—viz., 56 males and 106 females, or 7·7 per cent. of the average number resident. The deaths during the year amounted to 167, or 8 per cent. as calculated on the same basis. Of the deaths seven were due to renal disease, nine to colitis, 13 to cerebral softening, 18 to cardiac disease, 19 to pulmonary and other forms of tuberculosis, 46 to general paralysis of the insane, and the rest to other causes. The Commissioners in Lunacy state in their report that the general scheme and management of the asylum deserved favourable commendation, that the patients appeared to be well dressed and well cared for, that the day-rooms and dormitories were bright throughout, and that the medical-case books were kept in a highly satisfactory manner. They recommend that in case of fire the high level water-tank should be used. The committee of management states in its report that plans have been prepared and adopted for the erection of a hospital villa to accommodate 50 male patients and the necessary staff. The internal decoration of the asylum is now complete.

London County Asylum, Horton (Report for the year ending March 31st, 1904).—The average number of patients resident during the year was 1940, comprising 880 males and 1060 females. The admissions during the year amounted to 842—viz., 329 males and 513 females. Of these 824 were first admissions. Dr. F. Bryan, the medical superintendent, states in his report that an unusual number of the admissions have been patients of extremely troublesome character. The number of patients discharged as recovered during the year amounted to 218—viz., 76 males and 142 females, or 11·2 per cent. of the average number resident. The deaths during the year amounted to 245, or 12 per cent. as calculated on the same basis. Of the deaths six were due to colitis, 14 to renal disease, 15 to senile decay, 22 each to pneumonia and organic brain disease, 29 to pulmonary and other forms of tuberculosis, 45 to cardiac disease, 47 to general paralysis of the insane, and the rest to other causes. There were three inquests held during the year. The first was on a female patient who strangled herself by means of a small piece of cord torn from her nightgown and resulted in a verdict of "suicide during a state of unsound mind." The second was on a male patient who was alleged by his wife to have sustained ill-treatment at the asylum. The verdict was "death from natural causes, to wit, syncope produced from congestion of the lungs." The third was a male patient, a general paralytic who accidentally injured himself by fracturing his ribs and sternum and died the next day from bronchitis and emphysema. A verdict in accordance with the evidence was returned. The general health of the inmates has been good throughout the year and there were comparatively few cases of influenza. Painting and decorating of the asylum have been going on throughout the year. The committee of management states in its report that various portions of the building now in course of completion at the asylum include sanitary annexes to the airing courts, greenhouse, cricket pavilion, and half-padded rooms at the respective costs of £807 15*s.*, £990, £140, and £647. The painting and papering of the buildings have been in progress since April, 1903, and have cost £3005. The roads on the estate and the airing court paths are being put into thorough repair at a cost of £900. Precautions against fire and facilities for escape from an outbreak have received continued attention. The outer doors of the wards and dormitories have been altered to open outwards, the estimated cost of the work being £460, and the fire emergency exit doors have been constructed at a cost of £52. A second fireman has been appointed and the supply from the water mains has been increased at a cost of £75. The asylum has not been visited by the Commissioners in Lunacy in the year under review.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Sanitary Administration in the Itchen Urban District and upon the Prevalence of Enteric Fever therein, by Dr. H. TIMBRELL BULSTRODE.[1]—The urban district of Itchen is an area about two miles broad by two and a half miles long, situated on the east side of the estuary of the river Itchen. Southampton Water forms its southern boundary. In 1901 this district contained 2683 inhabited houses. Building is increasing, some 700 new dwellings having been put up since 1898, when the urban district was formed. The population consists mainly of artisans and others employed in Southampton who go daily to and from their work across the steam ferries. At Woolston and in a few other localities are "residential" houses of the larger kind. Enteric fever has lately shown a notable prevalence in this district. The figures for notified cases of this disease in each year from 1899 to 1903 are respectively 17, 12, 63, 52, and 65. The last three numbers appear extremely high for a population of about 13,000 persons. It is possible that some of the recent increase has been more apparent than real, for the reason that a larger proportion of mild cases of enteric fever, especially in children, have been notified than was formerly the case. This is suggested by the very low case mortality, the recorded deaths from enteric fever during the five years in question being three, one, two, two, and two only. But however this may be, it is obvious that the prevalence of the disease has become a serious question for the district. Dr. Bulstrode considers in his report the possible operation of various causes of spread of enteric fever. There seems no reason to suspect the water-supply, which in most instances is derived from the mains of the South Hants Waterworks Company. Inquiries with regard to milk, shell-fish, and other food consumed by the persons attacked had not been made with much regularity by the local officers concerned, but the data as far as they go do not tend to implicate particular food supplies. As regards sewerage it is remarkable that the increase of enteric fever has coincided with the provision of a system of sewers in the district in replacement of the cesspools which were previously in use and which had proved very objectionable. The house drains provided in connexion with the new sewers are in most cases satisfactory according to modern standards, but the sewers themselves leave a good deal to be desired. They must be leaky in places, as they admit a quantity of soil water, and although designed as part of a "separate system" they receive large volumes of rain water and occasionally have overflowed in times of storm. Purification of sewage at the outfall is also liable to be unsatisfactory, partly because of the excessive volume of the sewage and partly because of the manner in which septic tanks and filtration are employed at the new outfall works. It is possible that the extensive disturbance of already polluted soil in the neighbourhood of dwellings, wh [illegible] sewers were laid, has had [illegible] increase of enteric fever. [illegible] instances in which the disease has appeared in the same dwelling at intervals of several months or years also seems to support the suggestion of specific pollution of soil. Dr. Bulstrode indicates, however, certain other questions which should not be lost sight of. One is that in many cases direct infection was traced from person to person. The district has no isolation hospital and no disinfecting apparatus; moreover, dwellings in which cases of enteric fever occurred were not in all cases disinfected after the recovery of the patient. T[illegible] A[illegible] n[illegible] enforcement of local by-laws, and to other administrative matters.

---

[1] London, Eyre and Spottiswoode, Edinburgh, Oliver and Boyd; Dublin, E. Ponsonby. Price 6*d*.

On the Sanitary Circumstances and Administration of the [illegible] *the Penzance Regis*[illegible][2]—This report gives [illegible] vey of the sanitary conditions of two boroughs (Penzance and St. Ives), five urban districts (Madron, Paul, St. Just, Ludgvan, and Hayle), and West Penwith rural district. The population of the whole is nearly 50,000; the area under consideration, the most westerly portion of England, comprises agricultural land, market gardens, mines (now mostly disused workings), wild moorland, fishing villages, and small towns and scattered hamlets. The districts are dealt with separately and the sanitary condition and administration of each are reviewed. Among the principal recommendations which Dr. Low makes as a result of his survey are the following. In Penzance there is need for constant supervision of the stream which brings drinking water from Langen to the town in order to prevent pollution from adjoining farmhouses and land. In view of the recent prevalence and the heavy case mortality of diphtheria steps should be taken to secure bacteriological aids to diagnosis in this and other infectious diseases. At St. Ives measures are required to prevent the pollution of the Stennack stream, while similar pollution of the Tolcarne stream should be dealt with in the Madron district. The urban district of Paul, which includes the well-known villages of Newlyn and Mousehole, is reported to contain a number of objectionable and insanitary conditions. It requires an improved water-supply, proper scavenging, flushing to the [illegible] needs some approach to [illegible] which is now wanting. The [illegible] also should be provided with [illegible] water in replacement of the [illegible] re liable to pollution. The [illegible] in general a better sanitary record than the other districts concerned. It is satisfactory to find that many of the improvements of this district followed an inspection made by Dr. F. St. George Mivart in 1897 and it may be hoped that Dr. Low's report will have a similar [illegible] ea with which he deals [illegible] thout hospital accomm [illegible] and for each of these districts Dr. Low gives figures showing the extent to which scarlet fever, diphtheria, and enteric fever have been prevalent in recent years.

On the Sanitary State and Administration of the Newtown and Llanidloes Rural District, by Dr. R. A. FARRAR.—This is another administrative report relating to a large area situated in the valleys of the Severn and Tarannon and including the head waters of the Wye. The population of Newtown and Llanidloes district is about 12,000 As a result of detailed inspection Dr. Farrar recommends the appointment of an efficient inspector of nuisances and also of a district surveyor. At present there are two medical officers of health, each in general practice and responsible for a wide area. The salary which the district can afford would be [illegible] officer who was not [illegible] ports, however, that [illegible] whole rural district there would be an advantage in a single medical practitioner being appointed as its medical officer of health.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9181 births and 5955 deaths were registered during the week ending Jan. 7th. The annual rate of mortality in these towns, which had been 19·2, 19·4, and 22·4 per 1000 in the three preceding weeks, declined again last week to 19·9 per 1000. In London the death-rate was 18·5 per 1000, while it averaged 20 5 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 10·0 in Leyton, 10·5 in Hornsey, 10·8 in Smethwick, 12·6 in Walthamstow, 12·7 in King's Norton, 12·8 in Leicester, 13·0 in Northampton, and 13·4 in Bournemouth; the highest rates were 25·0 in Hanley, 25·8 in Huddersfield, 26·9 in Great Yarmouth, 27·8 in Coventry, 28·7 in Sunderland, 28·8 in Nottingham, 30·0 in West Bromwich, 31 4 in Grimsby, 31·8 in Stockton-on-Tees, and 37·4 in Merthyr Tydfil. The 5955 deaths in these towns last week included 399 which were referred to the principal infectious diseases, against 421, 399, and 475 in the three preceding weeks; of these 399 deaths, 123 resulted from measles, 97 from whooping-cough, 70 from diphtheria, 40 from scarlet fever, 39 from diarrhœa, 27 from "fever" (principally enteric), and three from small-pox. No death from any of these diseases was registered last week in Croydon, Brighton, Reading, Great Yarmouth, West Bromwich, Smethwick, Aston Manor, Coventry, or Rotherham; the highest death-rates from the principal infectious diseases were recorded in St Helens, Grimsby, Nottingham, Stockport, Preston, Stockton-on-Tees, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in East Ham, Plymouth, Burton-on-Trent, Grimsby, Nottingham, Middlesbrough. Stockton-on-Tees, and Merthyr Tydfil; from scarlet fever in Southampton and Northampton; from diphtheria in East Ham, Rochdale, Bradford, and Stockton-on-Tees; from whooping-cough in Norwich, Grimsby, Nottingham, Preston, South Shields, and Tynemouth; and from diarrhœa in Handsworth (Staffs.), Derby, and Merthyr Tydfil The mortality from "fever" showed no marked excess in any of the large towns. Of the three fatal cases of small pox registered in these towns last week one belonged to Oldham, one to Burnley, and one to Bradford The Metropolitan Asylums hospitals contained 18 small-pox patients at the end of last week, against 6, 14, and 17 at the end of the three preceding weeks; one new case was admitted during the week, against two, nine, and five in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2403, 2393, and 2386 on the three preceding Saturdays, had further declined to 2308 on Saturday, the 7th inst.; 187 new cases were admitted during the week, against 242, 242, and 201 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 387, 416, and 521 in the three preceding weeks, declined again last week to 443, but were eight above the number in the corresponding period of last year. The causes of 97, or 1·6 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Leicester, Hull, Newcastle-on-Tyne, and in 35 other smaller towns; the highest proportions of uncertified deaths were registered in Reading, Birmingham, Grimsby, Liverpool, St. Helens, Manchester, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 22·6, 21·2, and 21·6 per 1000 in the three preceding weeks, declined again to 20·6 per 1000 during the week ending Jan. 7th, but was 0·7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15·4 in Leith and 16·3 in Greenock, to 21·3 in Perth and 22·8 in Glasgow. The 690 deaths in these towns last week included 37 which were referred to whooping-cough, 14 to measles, 13 to diarrhœa, eight to "fever"

---

[2] Ibid, price 1s.

(including one case of typhus), four to diphtheria, and three to scarlet fever. In all, 79 deaths resulted from these principal infectious diseases last week, against 80, 90, and 78 in the three preceding weeks. These 79 deaths were equal to an annual rate of 2·4 per 1000, which was 1·1 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 32, 31, and 40 in the three preceding weeks, declined again last week to 37, of which 26 occurred in Glasgow, two in Edinburgh, two in Aberdeen, two in Paisley, and two in Greenock. The deaths from measles, which had been 17, 19, and 20 in the three preceding weeks, decreased to 14 last week, and included seven in Aberdeen, three in Glasgow, two in Edinburgh, and two in Leith. The fatal cases of diarrhœa, which had been 16, 25, and 12 in the three preceding weeks, rose again last week to 13, of which six were registered in Glasgow, four in Edinburgh, and two in Dundee. The deaths from "fever," which had been six, eight, and two in the three preceding weeks, increased again to eight last week, and included four in Glasgow and one of typhus in Aberdeen. The fatal cases of diphtheria, which had been seven, five, and two in the three preceding weeks, rose again last week to four, of which three occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 206, 174, and 184 in the three preceding weeks, declined last week to 182, and were 31 below the number in the corresponding period of last year. The causes of 35, or more than 5 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·3, 24·5, and 25·0 per 1000 in the three preceding weeks, further rose 25·6 per 1000 during the week ending Jan. 7th. During the past four weeks the death-rate has averaged 25·1 per 1000, the rates during the same period being 19·0 in London and 18·2 in Edinburgh. The 186 deaths of persons belonging to Dublin registered during the week under notice were four in excess of the number in the preceding week, and included five which were referred to the principal infectious diseases, against 10, 12, and 26 in the three preceding weeks; of these, three resulted from measles, one from "fever," and one from diarrhœa, but not any from small-pox, scarlet fever, diphtheria, or whooping-cough. These five deaths were equal to an annual rate of 0·7 per 1000, the death-rates last week from the principal infectious diseases being 1·0 in London and 1·9 in Edinburgh. The fatal cases of measles, which had been six, ten, and 16 in the three preceding weeks, declined again last week to three. The 186 deaths in Dublin last week included 34 of children under one year of age and 45 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a slight decline from the respective numbers recorded in the preceding week. Nine inquest cases and seven deaths from violence were registered; and 65, or more than a third, of the deaths occurred in public institutions. The causes of ten, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1904.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·1 per 1000 of the population, estimated at 4,648,950 persons in the middle of 1904. In the three preceding months the rates had been 8·0, 9·0, and 7·2 per 1000 respectively. The rates were considerably below the average in Paddington, Kensington, the City of Westminster, St. Marylebone, Finsbury, and the City of London, while they showed the largest excess in Hammersmith, Hackney, Bethnal Green, Poplar, Wandsworth, and Woolwich. The notified cases of small-pox, which had been one and six in the two preceding months, further rose last month to 16, of which seven belonged to Deptford, six to Woolwich, and one each to St. Pancras, Bethnal Green, and Wandsworth. The Metropolitan Asylums hospitals contained 17 small-pox patients at the end of last month, against three, one, and three at the end of the three preceding months. Scarlet fever was slightly less prevalent during December as compared with the preceding month; among the various metropolitan boroughs this disease showed the highest proportional prevalence in Hammersmith, Bethnal Green, Battersea, Wandsworth, Camberwell, and Deptford. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals at the end of the month was 2349, against 2127, 2662, and 2566 at the end of the three preceding months; the weekly admissions averaged 233, against 311, 359, and 249 in the three preceding months. The prevalence of diphtheria showed a considerable decline last month; this disease was proportionally most prevalent in Hackney, the City of London, Bethnal Green, Stepney, Poplar, Southwark, and Woolwich. The Metropolitan Asylums hospitals contained 800 diphtheria patients at the end of last month, against 871, 940, and 893 at the end of the three preceding months; the weekly admissions averaged 99, against 131, 139, and 123 in the three preceding months. The prevalence of enteric fever showed a slight diminution during December last; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in St. Pancras, Hackney, Holborn, Finsbury, Bethnal Green, and Greenwich. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 237, 225, and 178 at the end of the three preceding months, had further fallen to 159 at the end of last month; the weekly admissions averaged 22, against 45, 25, and 25 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Holborn, Bethnal Green, Southwark, Camberwell, and Deptford. The 22 cases of puerperal fever notified during the month included three in Hammersmith, three in Bethnal Green, three in Lambeth, two in St. Pancras, two in Poplar, and two in Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the four weeks ending Dec. 31st the deaths of 6555 persons belonging to London were registered, equal to an annual rate of 18·4 per 1000; in the three preceding months the rates had been 14·0, 14·3, and 14·6 per 1000. The lowest death-rates in London last month were 12·8 in Hampstead, 13·4 in Stoke Newington, 14·0 in Woolwich, 14·9 in Deptford, 15·0 in Greenwich, and 15·1 in Lewisham; while the highest rates were 21·7 in Stepney, 21·9 in Holborn and in Bethnal Green, 23·9 in Bermondsey, 25·0 in Finsbury, and 25·5 in Shoreditch. The 6555 deaths from all causes included 389 which were referred to the principal infectious diseases; of these, 124 resulted from measles, 33 from scarlet fever, 65 from diphtheria, 80 from whooping-cough, 28 from enteric fever, and 59 from diarrhœa. No death from any of these diseases was recorded last month in Stoke Newington or the City of London; the lowest death-rates from the principal infectious diseases in the aggregate occurred in Kensington, the City of Westminster, Holborn, Camberwell, and Deptford; and the highest rates in Hammersmith, Fulham, Finsbury, Shoreditch, Bethnal Green, Poplar, and Bermondsey. The 124 fatal cases of measles showed a decline of 107 from the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Islington, Hackney, Finsbury, Shoreditch, Bethnal Green, and Bermondsey. The 33 deaths from scarlet fever were 19 below the corrected average number; among the various metropolitan boroughs this disease showed the highest proportional mortality in St. Marylebone, Shoreditch, Bermondsey, Wandsworth, and Woolwich. The fatal cases of diphtheria numbered 65 last month, against an average of 173 in the corresponding period of the ten preceding years; the highest death-rates from this disease occurred in Hammersmith, Hackney, Bethnal Green, Poplar, Lambeth, Lewisham, and Woolwich. The 80 deaths from whooping-cough showed a decline of 39 from the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Hammersmith, Fulham, St. Marylebone, Shoreditch, Bethnal Green, Southwark, and Bermondsey. The 28 fatal cases of "fever" showed a decline of 39 from the average number in the corresponding periods of the ten preceding years; the greatest proportional mortality from this

* Including membranous croup

disease occurred in Hampstead, Hackney, Holborn, Shoreditch, and Battersea. The 59 deaths from diarrhœa were slightly in excess of the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Hammersmith, Fulham, Bethnal Green, Stepney, and Poplar. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was more than 43 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 136 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Hampstead, Stoke Newington, the City of London, and Deptford; and the highest rates in Kensington, Hammersmith, Fulham, Chelsea, Hackney, Shoreditch, and Bermondsey.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon James Charles Francis Whicher has been placed on the Retired List at his own request (dated Jan. 1st, 1905).

The following appointments are notified:—Fleet Surgeon V. G. Thorpe to the *Victorious*. Staff Surgeon T. C. Meikle to the *Majestic*. Surgeons: C. J. E. Cock to the *Vernon* for the *Furious*; J. Whelan to the *Vivid*; T. H. Vickers to the *Wildfire* for the *Endymion*; J. Lightfoot to the *Excellent*; N. J. Roche to the *Vivid* for Plymouth Hospital; W. H. Thomson to the *Russell*; G. M. D. Richards to the *Fire Queen*; A. D. C. Cummins to the *Drake*, on recommissioning, and H. Woods to the *Vivid*, to be lent to the *Circe*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel R. H. Forman joins at Woolwich. Captain J. M. Buist is under orders for service in South Africa. Captain A. C. Lupton now at Hounslow, is to be attached to the North-Eastern District (Headquarters, York). Surgeon-Lieutenant-Colonel J. Magill, from the Coldstream Guards, to be Lieutenant-Colonel, vice J. I. Routh, promoted, with seniority next above P. H. Johnston, C.M.G. (dated Dec. 3rd, 1904). Captain W. J. P. Adye-Curran is placed on temporary half-pay on account of ill-health (dated Dec. 23rd, 1904). Captain A. J. M. Cuddon-Fletcher resigns his commission (dated Jan. 11th, 1905) Lieutenant L. Cotterill to be Captain (provisionally) (dated Dec. 5th, 1904).

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions among officers of the Indian Medical Service:—*Bengal Establishment:* Majors to be Lieutenant-Colonels (dated Oct. 1st, 1904): John Tasman Waddell Leslie, David Prain, Arthur Thomas Bown, Upendra Nath Mukerji, and William Locking Price.

The King has also approved of the retirement from the service of the undermentioned officers:—Surgeon-General David Sinclair, C.S.I. (dated Nov. 15th, 1904); Colonel Bartholomew O'Brien (dated Dec. 3rd, 1904); and Lieutenant-Colonel William Locking Price (dated Dec. 4th, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (*Volunteers*): 1st Fifeshire: Supernumerary Surgeon-Major (Honorary Captain in the Army) S. Linton resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated Jan. 7th, 1905). 2nd East Riding of Yorkshire: Surgeon-Lieutenant A. W. Scott to be Surgeon-Captain (dated Jan. 7th, 1905). *Rifle*: 4th Volunteer Battalion the Royal Fusiliers (City of London Regiment): Supernumerary Brigade-Surgeon-Lieutenant-Colonel W. D. Waterhouse (Senior Medical Officer, 2nd London Volunteer Infantry Brigade) is granted the honorary rank of Surgeon-Colonel (dated Jan. 7th, 1905).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Manchester Companies: The undermentioned Lieutenants to be Captains: H. G. Parker (dated Jan. 7th, 1905), W. R. N. Smithard (dated Jan. 7th, 1905), and C. W. S. Saberton (dated Jan. 7th, 1905).

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on Jan. 10th, Sir J. Dick, K.C.B., being in the chair, the sum of £90 was distributed among the several applicants.

JANUARY ARMY ORDERS.

An abstract of Royal Warrant, Instructions, Regulations, &c., promulgated to the army on Jan. 1st has been published in the different service journals, from which it would appear that these cover a wide extent and more or less concern every branch of the service down to the announcement of the fact that the short-lived *Army Journal of the British Empire* has ceased to exist.

DEATHS IN THE SERVICES.

Brigade-Surgeon James Dow Sainter recently at Chester Villa, Craigellachie, aged 70 years. He joined the army as an assistant surgeon in 1859 and served with the Cavalry Division throughout the campaign of 1860 in China. After service in India he retired in 1880.

THE WAR IN THE FAR EAST.

The year 1905 has opened with gloomy prospects, so far as can be seen, for the Russian army in the Far East. When writing last week we said that while General Stoessel's heroic defence of Port Arthur had compelled the respect and the admiration of all, friends and foes alike, the news of the capitulation of the beleaguered fortress had given rise to an intense feeling of relief, in that an end had come at last to the sufferings and further futile sacrifice of life on the part of its devoted garrison. Its complete surrender has since taken place and 878 officers, with some 23,000 or 24,000 rank and file, have been handed over to the Japanese authorities. Of the 878 officers about half have given their parole. Apparently nothing could have exceeded the mutual courtesy and the good feeling exhibited by the rival generals—General Nogi and General Stoessel—at their meeting or the consideration, kindliness, and respect shown by the Japanese to the Russian troops as they marched through the lines of the investing army. Among those who marched out were 100 medical officers. According to Japanese estimates the total Russian casualties during the siege of Port Arthur amounted to 25,000. It does not seem to be quite clear, however, whether the total number surrendering at the end of the siege is inclusive or exclusive of the sick and wounded. We do not yet know what were the total casualties incurred by the besieging Japanese in their various assaults but these were undoubtedly largely in excess of those of the besieged garrison. It is reported that the Japanese since September last had prepared medical supplies for 20,000 men and these supplies are now proceeding by railway from Dalny to Port Arthur. Very many hospital attendants together with stores have been sent by the Japanese into the place. The Chinese have already set to work to rebuild their houses, while large parties are working everywhere burying the dead. It is much to be regretted that, owing to some misunderstanding which has since been satisfactorily explained, H.M.S. *Andromeda*, which had very promptly left Wei-hai-wei on receipt of the news of the fall of Port Arthur with stores, provisions, surgeons, and surgical staff to succour the Russian sick and wounded, failed to effect a landing. Scurvy was widely prevalent among the troops and in Port Arthur during the siege diseases of various kinds had made great ravages among them. Dysentery, typhus (typhoid fever?), and scurvy were the main causes of death. The ghastly spectacle presented inside the town and the fortress after their surrender fully bore out General Stoessel's despatch of Dec. 28th, 1904. It suffices to say that nothing could well have been worse than the state of things to which the besieged had been reduced. Of the original garrison of 35,000 nearly one-third had died and less than an eighth were capable of carrying arms. With regard to the belligerent armies confronting one another on the Shaho the dead-lock still continues, at any rate so far as any important or decisive movements are concerned. The *Wochenblatt* has collected information regarding the Manchurian armies as to the losses in killed, wounded, and missing in certain actions and operations. The Russian statistics are taken from the *Siberian Medical Notes*. From these it would appear that the Russian total of 70,354 includes 341 officers and 8730 men killed, 1506 officers and 49,626 men wounded, and 66 officers and 10,085 (mostly killed) missing. Apart from the achievement of some striking military success on the part of the Russians, which would, of course, upset all calculations, it seems to us that everything hinges on the question of supply. Unless an army in the field, and especially in a winter campaign, can be well fed and clad it cannot be kept in health and what may be termed fighting fettle. The Russians have, we believe, been very successful hitherto in their commissariat arrangements. Can these be maintained, with a sufficient supply of ammunition also, on the railway service which they have, or hope soon to have, at command?

The special committee of the Grand Duchess Elizabeth Theorodovni has received from General Kuropatkin a telegram in which he observes that from the beginning of the war to Dec. 13th, 1904, 1090 officers and 19,815 privates have been sent back to Russia; of these 520 officers and 5085 privates were wounded. Of the total number of privates sent home, 2897 had their discharge from the service because of unfitness through their wounds, and 5999 were released from service for one year.

Correspondence.

"Audi alteram partem."

THE ASYLUM MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—Your correspondent "M.B.," in the issue of THE LANCET of Dec. 31st, 1904, p. 1888, draws attention to a great blot in asylum organisation—viz., the poor pay and the enforced celibacy of the second medical officer who often is, and always should be, the deputy medical superintendent. The medical staffs of asylums in England are still far from adequate to the work the [illegible] favourably with those p[illegible] asylums. This relative [illegible] by the vast amount of statutory clerical work in the English asylums which occupies much time and diverts attention from more important matters. If the second and third medical officers in our large asylums were paid and accommodated in a manner that would admit of their being married much good would result in the treatment of the insane. Little progress in this direction can be hoped for until the treatment of the insane is placed under the direction of a "Minister of National Health."

The Lord Chancellor under existing conditions is physician-in-chief to 100,000 insane sick persons, with the result that the Lunacy Commission is not organised as a medical but as a legal body, in which the medical element is so outnumbered and so overburdened that it is practically powerless. [illegible] lums is to place [illegible] bad second. U[illegible] and asylums placed under a medical authority there is no possibility of reform in this or many other much more grievous methods of lunac[illegible]

I [illegible]

Jan. 9th, 1905.

To the Editors of THE LANCET.

SIRS,—I am glad to find that the grievances of assistant medical officers in asylums for the insane have at last been given publicity in the columns of THE LANCET, and while "M.B.'s" letter in your issue of Dec. 31st seems to refer chiefly to county asylums, from my own experience the same restrictions seem to apply to those in private asylums. In the latter the medical superintendent has an even greater power than he has in the former. "M.B.'s" letter, had it been written by myself, could hardly have expressed my experience more exactly. Leave of absence ought not to be subject to the moods of the medical superintendent. He can, and in most instances does, go out and about as he thinks fit, but if an assistant medical officer wishes to go off duty he has to ask the superintendent before he can do so. Again, leave ought not to be confined to so many hours a day or week, but one ought to be able to reckon on having a night off once a month, as is the case with nurses and attendants in some asylums, and a week-end once a quarter would not be asking too much when one takes into consideration the nature of [illegible] Again, a superior officer o[illegible] with the prescriptions of [illegible] frequently seen done and that without any sort of consultation between the two. In fact, I have known a superior officer tell his inferior [illegible] in spite [illegible] disease [illegible] that giv[illegible] exists i[illegible] inquire into the conditions under which assistant medical officers work, as they have done in the past in the case of nurses and attendants.—I am, Sirs, yours faithfully,

Jan. 3rd, 1905. MEDICO.

THE TREATMENT OF PARALYSIS IN CHILDREN.

To the Editors of THE LANCET.

SIRS,—I have read with much interest Dr. Alfred A. Mumford's article in THE LANCET of Jan. 7th, p. 16, on the treatment of paralysis in children, which I am sure will be very useful by calling attention to the advantages of systematically encouraging voluntary movement in this class of cases. I am convinced that this is by far the most efficacious method of treatment and I thoroughly agree with Dr. Mumford's statement that "every fresh effort made by the child, and especially every successful effort, in achieving a new organised movement becomes in its turn a very potent therapeutic agent." It is astonishing to observe at how early an age a child can be taught to make systematic movements and I have for many years been in the habit of treating quite young children by having them taught to practise voluntary [illegible] In a book on orthopæd[illegible] "The consequence of t[illegible] ance of the muscular c[illegible] the paralysed muscles having no opposition to their action become gradually shortened and their function being in abeyance they also lose activity. Thus the paralysis of one set of muscles leads indirectly to the disuse and loss of power in others and a limb may be rendered almost useless by the paralysis of but a few of its more important muscles."

I would point out, moreover, that in partial paralysis of a limb many movements can be produced by practice in the vicarious action of the muscles, the functional activity of which is unimpaired. The most efficient means of developing the power of an enfeebled muscle is its moderate use alternating with its complete rest. A little ingenuity exercised in the application of this principle to cases of paralysis in children will generally be well rewarded by the resulting improvement. The methods recommended by Dr. Mumford are excellent and I can confirm his experience of the usefulness of the progression on all fours. Of course, deformities which mechanically interfere with the use of limbs must be remedied by tenotomy or other means, but a long experience leads me to protest against applying to young children cumbersome instruments of support which often prevent rather than assist muscular development. The children should be daily encouraged to the voluntary use of the weak muscles, so that the first return of voluntary power, however slight, may be exercised and developed.

I am, Sirs, yours faithfully,
WARRINGTON HAWARD.

Green street, Grosvenor square, W., Jan. 10th, 1905.

THE RECENT DISCUSSION ON CHLOROFORM ANÆSTHESIA.

To the Editors of THE LANCET.

SIRS,—May I be allowed to add a few words in confirmation of Dr. F. W. Hewitt's views on the inadequacy of a fixed percentage of chloroform vapour for anæsthetising all types of the human subject? In addition to muscular and plethoric persons, alcoholics, and heavy smokers there are other patients who exhibit a very considerable resistance to the effects of small quantities of chloroform: (*a*) those who have suffered from tropical fevers—and during the induction of anæsthesia especially; (*b*) the emphysematous; and (*c*) the febrile. With regard to the first class I do not know that it has been pointed out before that previous attacks of malarial and other tropical fevers render their subjects extremely difficult to anæsthetise, but in my experience such is the case, and I have records of a number in whom even a concentrated vapour of chloroform was barely potent enough to produce muscular flaccidity during abdominal operations and in whom the use of a Junker's apparatus alone was a mere farce. Owing to the immobility of the chest walls in emphysematous patients the interchange of gases in the air sacs is effected largely by slow diffusion from the upper air passages and I have found that during induction of chloroform anæsthesia a resistance to the effect of the vapour much above the normal is due to this cause. Highly febrile patients may also exhibit undue resistance to small doses during induction on account of the decreased solubility of gases in liquid blood as the temperature of the latter increases.

I have long held the view from practical experience that chloroform does not prevent the transmission of nerve stimuli and the occurrence of reflex respiratory spasms so completely as ether, and in operations involving dilatation of the cervix uteri and sphincter ani or much dragging on pelvic and abdominal organs I frequently resort to ether when such spasms arise under chloroform in order to abolish them.

The form of obstructive stertor which Dr. Hewitt designates reflex spasmodic tongue retraction frequently occurs under chloroform in obese and plethoric subjects and is vibratory or rhythmic in character. It commences when a strong surgical stimulus is applied and ceases when it is discontinued. Failure to recognise the nature and causation of obstructive stertor due to reflex laryngeal spasm and to reflex tongue retraction may be readily understood when admitted by surgeons and physiologists who are not engaged in constantly administering anæsthetics to the human subject but shows a lack of accurate observation in any administrator of experience. So greatly do I desire to emphasise the importance of attending to the state of the corneal reflex and other clinical symptoms and of relieving stertor and even slight asphyxial factors directly they arise in chloroform anæsthesia, and as compared to these duties so trifling is the ease of learning dosage with very simple apparatus, that I regard the use of so-called percentage inhalers for chloroform with apprehension for the security of the public and the misguided practitioner who uses them.

I am, Sirs, yours faithfully,
H. BELLAMY GARDNER.
Mansfield-street, Portland-place, W., Jan. 3rd, 1905.

THE TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—I was very interested to read in THE LANCET of Dec. 31st, 1904, p. 1825, the very able address on the treatment of phthisis by Dr. Hector W. G. Mackenzie. There are, however, some points in it with which, as a sanatorium physician of some experience, I feel I must disagree. Dr. Mackenzie says that the good results obtained in English sanatoriums go far to show that our English climate is not unfavourable to lung patients and that even winter residence in England is not incompatible with an open-air life. Now I go so far as to say that these results prove conclusively that our home climate is as favourable to the proper carrying out of the treatment as that of any place abroad.

In Falkenstein Sanatorium, Germany, where I was first a patient and afterwards an assistant doctor, the winters are foggy, dull, and very rainy, with a little snow, yet the experience of many years has shown that patients do best there in the winter months. Dr. Mackenzie, I see, still clings to the myth that very high and dry altitudes are best for the consumptives. I am convinced, however, that a great many physicians, experienced in sanatorium work and otherwise, will agree with me when I say that results do not bear this out. On the contrary, these conditions are in a large proportion of cases distinctly harmful. At these high altitudes the tendency to hæmoptysis, heart trouble, &c., is enormously increased even in the early stages of the disease. Again, patients have not only the initial long journey to go through but they are frequently unable to complete the cure there. Generally they have to leave in the summer months—a fact which entails the worry and risk of travelling and changing to an absolutely different climate. In my opinion, too, a patient cured in his own country has a far better chance of keeping in good health than one cured elsewhere, because his body has been trained to withstand the variabilities of the climate in which he has to pass his life Experience has also shown that patients cured in places like Davos have a much greater tendency to relapse when they go down to lower levels. I am glad that Dr. Mackenzie has given the weight of his great authority and experience against the practice of stuffing—a method of treatment which is, to say the least of it, most unscientific.

I am, Sirs, yours faithfully,
A. C. FALKINER, M.B. Dub.
Portbury, Somerset, Jan. 2nd, 1905.

THE ORGANISMS OF VARIOLA, VACCINIA, AND VARICELLA.

To the Editors of THE LANCET.

SIRS,—A case recorded by Dr. Richard Rolfe under the title of "A Case of Variola following an Unusual Course"[1] is of extreme interest and excites philosophical speculation as to the inner workings of the disease processes undoubtedly present. The researches of Guarnieri, Jackson Clarke, Calkins, and more recently of Dr. W. E. De Korté,[2] strongly point to protozoal organisms being the causal agents of variola, vaccinia, and varicella. Apparently one common organism running on different evolutionary lines is to be found in the pocks of these three affections, and now that Dr. De Korté[3] claims to have cultivated the organism in pure culture further scientific light on the subject may be expected at an early date.

I have long felt the conviction—based on clinical and epidemiological observations—that vaccinia, variola, and varicella are the products of the life-processes of one common type of organism existing under different evolutionary conditions. It appears as if we were on the verge of scientific confirmation of this speculation but many observations must yet be made before sufficient facts will be available for critical judgment and acceptance. I venture to suggest that in Dr. Rolfe's case the illness from Nov. 11th to 14th was undoubtedly an abortive attack of variola. In the light of Dr. A. E. Wright's researches this attack probably induced a "negative phase of immunity." The vaccine lymph inoculated on Nov. 16th contained the same pathogenic type of organism as that of variola but under different evolutionary conditions. This organism was stimulated by the abortive attack of small-pox to produce similar lesions to those found in variola; or, on the other hand, the variola organisms lying latent in the patient were stimulated into unusual activity by the vaccine organisms. The skin lesions appeared on the third day after vaccination. Further, the interaction of the two strains of the protozoal (?) organism evidently modified the ordinary phenomena of vaccination. My own practical experience teaches me that if an unvaccinated person attacked with small-pox *be vaccinated on the first day* of illness the skin lesions of small-pox may appear as usual on the third day, while those of vaccinia may run an almost normal course. I am inclined to look upon the rash in Dr. Rolfe's case as being more of the nature of a "vaccination rash" induced largely by the prior abortive attack of small-pox than as a genuine case of modified variola. But I express this opinion with all due diffidence. A clinical point of importance which would put this view out of court would be the presence of dark brown or black discoid scabs appearing on some of the lesions, supplanting the stage of suppuration.

In April, 1902, I saw a youth, aged 17 years, who had been revaccinated a few weeks previously but had in the meantime been in contact with a case of small-pox. He exhibited a hard shotty eruption of the face (not the forehead) and wrists and one papule on the arch of one foot but no constitutional symptoms were noted. The papules faded without passing through a vesicular stage. The case was isolated as possibly variola though I inclined to the diagnosis of a varioloid vaccination rash.

The record of a case of chicken-pox which shows some of the difficulties which beset medical men in making specific diagnoses may not be deemed unnecessary. On June 3rd, 1902, I was asked to see in consultation an unvaccinated boy, aged nine years. I found copious semi-puriform vesicles on the trunk and limbs, including two on the thenar eminence of the right thumb and five on the sole of the left foot. Several pocks were also present on the dorsal aspect of each foot. Here and there on the trunk and limbs "constellations" of vesicles were noted On the face were observed papules and a few vesicles A history was obtained of two previous cases of chicken pox in the house The patient had complained of backache and nausea on May 31st but had not been very sick The temperature when I saw him was normal There were very few pocks on the scalp and the lesions were more abundant on the upper parts of the limbs than on the lower The balance of evidence was therefore in favour of a diagnosis of chicken pox but we were getting sufficiently near the border line in symptoms to take all due precautions as to isolation of the patient and to urge vaccination or revaccination of contacts

Jan 7th 1905 Medical Officer of Health Southend on Sea

THE EVOLUTION OF MAN'S DIET

To the Editors of THE LANCET

SIRS,—I quite agree with Dr J Sim Wallace that we moderns could greatly increase our power to cope with coarse vegetable foods if we from early years accustomed ourselves to them I believe however, that even then we should, in respect of this power, fall far below the apes Not the most primitive race of man could subsist on the natural diet of these creatures, and, though very little anatomical difference can be discovered between the digestive organs of man and the

postulate a wide difference in

two Though the vegetable f

in cellulose than our own, yet even they would appear to

[illegible] removing the pips of a choice apple before eating it

I must doubt whether the bitter, acid, and acrid principles which enter so largely into the natural diet of the anthropoids facilitate in any substantial degree the digestion of cellulose, but that they may play a useful part in digestion and nutrition and that the diet of us moderns is all too deficient in them I can well believe Indeed, I venture to think that here Dr Wallace makes a most valuable suggestion There can be no doubt that both man and the apes have an instinctive liking for substances of this kind Dr Mitchell finds that when a sick chimpanzee is off its food and when every other plan has failed he can induce the invalid to eat by flavouring its viands with rhubarb, and we know that children often display a violent craving for unripe fruit in rebellious protest, it would seem, against the soft bland and generally alkaline food on which they are nowadays nurtured Whether this bland diet is also, as Dr Wallace suggests responsible for their craving for sugar is well worth being put to the test

I am, Sirs, yours faithfully,
Wimpole street W, Jan 8th 1905 HARRY CAMPBELL

To the Editors of THE LANCET

SIRS,—Dr Harry Campbell s views as to the "evolution of man's diet' must have induced some of your readers to be more particular as to diet in the treatment of disease and so far will do good but the study of diet is a most complex subject and deserving the attention of every member of the profession It is a subject in which everyone ought to take an interest, since not only the body but the mind depends upon what we put into the stomach Drugs have dominated our profession since the days of the alchemists and now there

that we are suffering from having departed from the diet of primitive man before fire was stolen from the gods and when he ate only fruit and nuts his natural food Our food now (apart from the flesh of animals which causes so much disease, directly and indirectly) consists very largely of starch, the conversion of which into dextrine is a great tax on the energy of the digestive system Good cooking may lessen the danger of eating such food, but however well cooked our food ought to be masticated thoroughly and kept in the mouth until into the fluid form, nothing except fluid being allowed to enter the stomach With practice in chewing food the tongue becomes like a filter that will allow no solid substance to pass Such chewing takes time but it is time well spent and food so chewed will go twice as far as food bolted, as it is too apt to be Scientific observations on the value of such chewing are much needed and when made will be most valuable in the study of dietetics

I remain, Sirs, yours faithfully,
JOHN HADDON, M D Edin
Denholm Hawick N B Jan 8th 1905

THE L S A QUALIFICATION AND MEDICAL APPOINTMENTS

To the Editors of THE LANCET

SIRS —It is refreshing to find a member of the profession who is not an L S A wielding his pen in favour of justice being done to the holders of this much belittled diploma in the matter of hospital appointments, &c That the professional equipment of the Licentiates of the Apothecaries' Society is of a satisfactory character is shown by their success in the competitive examinations for the navy and army I have before me a table[1] showing percentages of successes of holders of various degrees and diplomas at these examinations, from which I extract the following —

L S A alone	70	per cent	successes
Scottish Conjoint alone	39	,,	,,
Irish	34	,,	,,
Manchester degree	62	,,	,,
Aberdeen ,,	54	,,	,
Edinburgh ,, ,,	50	,,	,,
Glasgow ,,	66	,,	,,
Dublin	45	,,	,,
Royal University degree alone	63	,,	,,

These navy and army competitions are the only post-graduate tests in which all candidates appear on equal terms and the results should I think, convince all impartial persons that the L S A is not the inferior practitioner that the holders of these other degrees and diplomas often represent him to be and that he is capable of more than holding his own in professional competition This being so, is it asking too much that the powers that be should give to the persons with this diploma proper and sufficient titles and that the ridiculous chatter about it being the lowest qualification for admittance to the Medical Register should cease? Is it not simple justice that all hospital appointments which are open to holders of Conjoint diplomas &c, *should be equally open to* the L S A ? Your correspondent "Not an L S A,' is quite right about the surgical examiners at the Apothecaries' Society being appointed by the General Medical Council, and I may add that it is the duty of these examiners (see Medical Act, 1886 Section 5 Paragraph 2) ' to secure the maintenance of such standard of proficiency in medicine, surgery and midwifery as is required under the foregoing provisions of this Act The effect of this clause is that *every* final examination for the L S A is conducted under the direct supervision of the General Medical Council s own appointed examiners who are responsible for the standard of efficiency The same conditions now apply to the L A H Irel At no other qualifying examinations whether for degrees or diplomas, are the interests of the public so carefully safeguarded Medical members of hospital boards have no excuse for ignorance on this subject and it is their duty to correct it in the lay members.

LOCAL IRRITATION AND CANCER.

To the Editors of THE LANCET.

SIRS,—Now that the parasitic origin of cancer has almost come to be regarded as an impossible theory it may not be without interest to remind your readers that the older authorities considered the systemic origin of cancer as being necessary to its local evolution. At the present time the opinion seems to prevail that a relation exists between cholelithiasis and cancer. In this connexion the most suggestive theory of the origin of cancer is that which has been propounded by Mr. J. H. Webb of Melbourne—viz., that cell proliferation is due to the deposition of cholesterine in the tissues, either locally from injury or some nutritional disturbance in the liver, associated with deficiency of the bile soaps which normally hold cholesterine in solution. For his conclusions and treatment I would refer those interested to my recently published pamphlet "On Some Methods of Hypodermic Medication in the Treatment of Inoperable Cancer," in which I also describe some cases of my own treated with hypodermic injections of Chian turpentine, the effect of which, there is reason to think, is also that of a solvent of cholesterine.

In the same way I suggest that the presence of glycogen in new growths may be due either to undue local deposition in the tissues or dependent on some nutritional disturbance in the liver or pancreas leading to cell growth. Incidentally I might mention that in two cases of malignant disease recently which have come under my notice one or other parent died from diabetes. This, together with the comparative infrequency of glycosuria and cancer in the same patient, as I believe, is suggestive of some alternation or antagonism between the two diseases. Chiefly, therefore, the underlying theory here put forward is that cell proliferation or alteration of type of division may be dependent on some systemic condition and local irritation determine site of growth. Continued reflection on this subject has led me to believe that in dealing with cancer something more than purely local treatment is indicated—that is to say, that after the surgeon has removed the source of local irritation represented by the primary growth there should follow treatment directed to the systemic origin of the disease. Were the lines of treatment I have indicated in my pamphlet to be carried out subsequently to operation it is reasonable to hope that recurrence might not so frequently occur. This opinion has been partly based on the experience gained in the treatment of cases of cancer where the disease has passed beyond the sphere of surgical relief. If palliative results can be obtained in such unfavourable cases as these it is only reasonable to conclude that where the conditions are favourable the results should be eminently better and the tendency to recurrence diminished. I am, Sirs, yours faithfully,

JOHN A. SHAW-MACKENZIE, M.D. Lond.
London, Jan. 2nd, 1905.

TICKS AND TICK-TRANSMITTED DISEASES.

To the Editors of THE LANCET.

SIRS,—To the list of countries mentioned by Dr. G. H. F. Nuttall in his paper at the Epidemiological Society[1] in which bovine redwater fever occurs, I can add the Republic of Colombia. It is prevalent in the south-western portion (and possibly elsewhere), i.e., far distant from Venezuela, which country Dr. Nuttall includes. Ticks also infest horses and dogs in the same districts, the former with oftentimes serious effects. Whether these are due merely to loss of blood or to some form of equine piroplasmosis such as is known in other countries I am unable to say.

I am, Sirs, yours faithfully,
M. D. EDER.

---

[1] THE LANCET, Dec. 24th, 1904, p. 1785.

CHICAGO.

THE DARK AND INSANITARY PREMISES USED FOR THE SLAUGHTERING OF CATTLE AND HOGS.—THE GOVERNMENT INSPECTION.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(*Continued from p. 52.*)

THE first or most obvious defect of the stockyards is the absence of slaughter-houses. Here living animals are treated in exactly the same manner as is ordinary raw material. The Chicago stockyards therefore consist of a number of factories instead of slaughter-houses. These various enterprises are grouped together on the same spot and work not in opposition but as "a combine" one with the other. Here the evident desire is to treat living animals as if they were bales of cotton, of wool, or of any other kind of raw material. What would have happened but for the intervention from Washington of the Federal Government and the prohibitive laws enacted by European States against Chicago products, it is appalling to conjecture. Left to themselves the organisers of this vast industry were not likely to consider that animals, whether living or recently slaughtered, are more liable than inorganic raw material to convey or to absorb germs of disease. That what is intended for food should be prepared in especially clean places is also insufficiently taken into account. The sole object seems to be to convert each animal into saleable product in the quickest and cheapest manner possible. For this the work has to be organised on a wholesale scale so as to pay the cost of labour-saving machinery and there must be the greatest possible subdivision of labour. In a word, the principles of modern industrialism have to be applied and there is no business in the world, not even at the Krupp works, where this done on a larger scale. Of course, all the private butchers have been bought up or driven out of existence for many a mile round by this huge monopoly. Private slaughter-houses were, and generally are, very defective when judged from the sanitary point of view; still they are preferable to slaughtering in factories. The number of animals killed is much smaller than in factories and this is done not upstairs but on the ground and in a little building like a stable where there is no difficulty in obtaining air and light. At the Chicago stockyards I was first taken to see the killing of pigs and found that outside the big factory buildings there are long, inclined, boarded passages up which the animals are driven. Thus the pigs are brought up to the height of the second floor. As they enter the main building each pig is caught by one of the hind legs. With rope and loop-knot and hook it is slung up, the head downwards and the neck exposed, at a convenient height for the slaughterer to strike. With great rapidity the suspended pigs are pushed on to a sort of passage about four feet broad where their throats are slashed open as they pass along. These rows of hanging pigs struggle violently, throwing out torrents of blood. Both sides of this death passage to the height of five feet are thickly caked with the blood of thousands of healthy and unhealthy pigs. Within less than a minute the dying pig reaches a long tank full of scalding water and in this the palpitating body is thrown, though life is probably not yet quite extinct. Standing in the damp and steam men armed with long prongs push the swine along. By the time when the hogs have floated down to the other end of the boiling-water tank they are sufficiently scalded for the bristles to be easily extracted. They are now put on a moveable counter or platform and as the hogs pass along other workers scrape the bristles off their backs. All this is done on the second floor of the building and there are suitable openings in the floor through which the blood flows to be collected and utilised below. At a subsequent stage the body is opened and the intestines are removed. Fortunately the law, not the local or State law, but the national or Federal law, stipulates that:—

> The head, tail, caul, or fat inclosed in the omentum of the animal and the entire viscera shall be retained in such a manner as to preserve their identity until after the post-mortem inspection has been completed, in order that they may be identified in case of the condemnation of the carcass. Should the carcass of any animal on the said post-mortem examination be found diseased or otherwise unfit for human food it shall be marked with a condemnation tag, the same to be attached with

According to the national law there must be two examinations—the ante-mortem and the post-mortem. The ante-mortem examination takes place in the cattle market when the animals are weighed while they are still the property of the farmers and cattle-rearers and before they have been purchased by the packers or provision dealers. The agents of

FIG. 5.

Scalding hogs.

he latter are consequently always on the look out and call he attention of the Government inspectors to any bad symptom or defect which they may detect. If at this stage the animal is condemned the loss falls on the farmer. If, however, the presence of disease is only discovered when the carcass is examined then the loss falls on the packer who had to buy the animal before he could kill it. So that while the packing-house interest is in favour of strict ante-mortem examination it stands to lose by the post-mortem examination. Nor is this latter easy to carry out considering the sort of superstitious fear that exists in America of anything which might be considered as "interfering with business." The consequence is that there is a staff of officials appointed by the authorities at Washington whose sole business it is to see that nothing shall be placed on the market as food which is not absolutely wholesome. As civil servants and as protectors of the public they should hold the highest position in the stockyards. This is a noble calling and by reason of the useful work which the veterinary surgeons perform and the scientific training which they have received they surely stand immeasurably above mere speculators in hogs' flesh. But there is a singular lack of the sense of dignity in the United States. This came specially under my notice at St. Louis where the grandeur of the World's Fair was largely spoilt by the undignified rowdyism and vulgarity that were allowed to prevail even within its precincts. At the Chicago stockyards I could not but feel scandalised and humiliated when I saw the foul and abominable premises in which the representatives of science, the representatives of the United States of America, the representatives of the majesty of the law, condescended to work daily in the accomplishment of their mission. This mission would be better accomplished if the veterinary surgeons, as members of a liberal profession and as representatives of a great country, refused to work in these noisome places. Such a course would at once stop the present abominations by compelling the hog merchants to reconstruct their premises. It is a very good thing that inspectors are appointed by the authorities at Washington but it would be better still if they were first sent to Berlin to learn not only how a slaughter-house ought to be managed and constructed but also to observe how those who have the honour of being intrusted with a public duty are more respected than business men, however rich.

Slaughtering, it need hardly be said, should be done on the ground, but the ground should be rendered water-tight by a special non-slippery, convex, and elaborately drained paving. The surrounding structure should be built exclusively of iron, glass, or enamelled brick. Of course there should be no upper floor and there should be ventilation above and on both sides That is how slaughter-houses in the technical sense of the term are built. At Chicago there are, I cannot repeat tc [illegible] all. The factories consist of [illegible] which might penetrate throu[illegible] kept clean cannot reach the centre of the buildings. Consequently a large proportion of the work has to be done by artificial light even in the brightest portions of fine summer days. Thus, for instance, I saw bullocks slaughtered in the following manner. The animals are brought up to a huge building which looks more like a lofty prison than a slaughter-house. As they approach the outer wall men strike them on the head with a mallet. Then a sort of wooden partition gives way and lets the half-stunned animals fall into the basement of the building beyond. As they come tumbling in men seize their hind legs, affix ropes, and they are strung up to some machinery above that moves them along with their heads hanging downwards. Sometimes, however, and before this can be done an animal jumps up and rushes about. It has then to be shot at the risk of the bullet striking an onlooker. When I inquired why a leather gear was not affixed to the bullock's head with a nail so placed in it that, however clumsy the stroke given, it would cause the nail to penetrate the brain and instantly

FIG. 6.

Removing hides

kill the animal, I was told that such a process would take far too much time. Indeed, so great is the hurry that the unfortunate animals are frequently not given time to die. First, they are dropped into the building, though some of them may be insufficiently stunned. Then, when strung up, the machinery carries the living animal forwards and men have to run after it to cut its throat, while others follow with great pails to catch the blood; and all this without interrupting the dying animal's journey to the part of the factory where the next process of manufacture begins. Sometimes the cattle are struck down and stunned more quickly than the men can pick them up and cut their throats, so they are left to live some time suspended in the air by their hind feet. The machinery carries forwards the animals that are hooked on to it regardless of their agony. On they go from stage to stage of manufacture and the men have to keep pace with them whether dead or alive. Quickly the throats are cut, no time can be lost to let the animals bleed, a man with a pail must walk by their side to catch the blood. Much of the hot blood is spilt over the man or over the floor; that does not matter so long as a small section of a minute is economised. In a short time the bullock, whether it has bled sufficiently or not, and while still warm, will reach one of the darkest, lowest, and worst ventilated portions of this huge and gloomy building. Here the entrails are taken out. The dirtiest work is done in the closest, the darkest, and the dirtiest place, instead of being carried on in the open air or under such slight shelter as would not prevent the free access of air and sunshine. It would be quite impossible to disinfect such premises. There are innumerable rafters, sharp angles, nooks, and corners where blood, the splashing of offal, and the sputum of tuberculous workers can accumulate for weeks, months, and years. It does not look as if the floors are ever really cleaned, though I am told they are occasionally scrubbed. Nevertheless, it is difficult to believe in any genuine cleanliness, for here is the evidence of the windows about which there can be no doubt and they are heavily caked with dirt. Where are the impermeable walls and floors which every day, and sometimes more than once in the course of the day, should be flushed out with the fire hose and so thoroughly scoured that not a speck of blood, dirt, or dust should remain? Where, again, are the portable fire and boiler which can be wheeled or carried up to any corner of the entire premises and where with hose a jet of steam under pressure can be thrown into the smallest crevice or crack? Thus with superheated steam disinfection is rendered doubly sure. In many towns of Europe where there are not nearly as many animals killed as at Chicago purifying machines of this description are used. Why are they unknown at Chicago? As Chicago is the greatest slaughter-place in the whole world the greatest possible precautions ought to be taken. The reverse, however, is the case and it is safer to buy meat from the small retail municipal slaughter-house of a petty provincial town than from the world-wide provision packers of Chicago.

An official of the Canners' Union assured me that more than two-thirds of the members of his union worked by artificial light. He had not himself seen daylight for many months and so far as the enjoyment of sunshine was concerned they might as well be miners working in a coal-pit. Yet if ever there was an occupation requiring plenty of daylight and fresh air it is that of cleaning, cutting up, preparing, and canning animal food. But the buildings are so large and square in shape that, as already explained, the light from the windows cannot penetrate to the centre; while machinery passing carcasses, furniture, fixtures, and partitions shut out the light from many of the places that it might otherwise reach. Yet it is obvious that work of this description—the manipulation of animal substance intended for food—should be done only in the broadest daylight and in the purest atmosphere. In these dark places the meat falls on the floor and comes in contact with the dirt from the boots of the workers and the bacilli from the sputum of a population among whom pulmonary tuberculosis is more prevalent than among any other section of the inhabitants of Chicago. Close at hand there are closets and they are in some places only a few feet from the food. These closets are at times out of order, deficient, defective, or even entirely devoid of flushing. They are all the more offensive as they are not sufficiently numerous for the large staff of workers who have to use them. This is especially the case in one of the rooms where soup is made for preserving in tins. In one department there were two closets, neither of which could be flushed, provided for 80 women. Little or no thought has been taken as to the welfare of the workers. It was only after much agitation that the work was more evenly distributed by killing during four instead of two days. Then there used to be no provision whatsoever for the workers' meals and they had to eat amid the filth in which they worked. Even to-day and after many protests and agitations there are no proper lavatories for the workers to wash themselves conveniently and to change some of their clothes before they begin handling the food which is sent from Chicago to all parts of the world. Indeed, it will be found that many of the workers hold the food which they produce in wholesome abhorrence. At the same time there is a great deal of bitterness of feeling and a consequent tendency to exaggerate. Besides, it is surprising how ignorant these people are concerning the special laws by which their industry is governed. For instance, I was told that diseased and condemned carcasses which were put in at one end of the destructor to be converted into manure were promptly extracted at the other end and sold as meat. Now, the rules issued by the United States Department of Agriculture, dated June 27th, 1904, give minute details as to what diseases necessitate the destruction of the carcass and article 9 is entitled "Tanking." The carcass destructor in America is called a tank and the legal stipulations are that—

> All condemned carcasses and parts shall be tanked as follows. After the lower opening of the tank has been sealed by an employé of the department the condemned carcasses and parts shall be placed in the rendering tank in the morning and immediately a sufficient force of steam be turned into the tank to destroy effectually the meat for food purposes before the killing for the day is completed; or the condemned portions may be placed in the rendering tank at the close of the day, or when the killing is suspended, and both ends of the tank sealed, after which steam shall be turned into the tank until the meat is destroyed. Wire and lead seals will be provided by the department for sealing tanks.
>
> A sufficient quantity of low-grade offal (uteri, floor scrapings, trimmings from gutters' benches, skimmings from catch basins, unemptied intestines, omasa, paunches emptied but not washed, &c.) shall be tanked with all condemned carcasses (except those tanked for lard) to effectually render the ultimate product unfit for human food, or, if such offal cannot be obtained, the carcasses may be thoroughly slashed with a knife, then saturated with kerosene and placed in the tank.
>
> The seals of tanks containing condemned material shall be broken by an employé of the department when the tank is emptied during regular hours and at other times satisfactory arrangements for the breaking of such seals shall be made with the inspector in charge.

When only a part of a carcass is condemned no portion of the carcass can be disposed of except in the presence of the Government inspector, so that when stories go round about the selling of diseased meat the persons who tell them are either deliberately inventing or more probably confusing an ordinary cauldron with the destroying tanks. Also I was told that bruised and rejected hams were nevertheless sold and put on the market by cheap butchers; or else the bone may be cut out and the discoloured portion of the flesh near to the bone removed, the rest being utilised. Again, when meat that has been put in brine for pickling is found to smell hollow needles are driven into the flesh and brine is pumped into the body of the meat. This saves the time of penetration and men have assured me that when the meat still retained an unpleasant odour the operation was repeated. Nevertheless, I find some difficulty in believing these stories. They are the tricks of trade of the petty dealer and it is hardly conceivable that a gigantic business would compromise itself for the sake of saving a few shillings' worth of meat. On the other hand, where thousands of pounds are to be economised, there is a deplorable display of unscrupulousness. When a carcass or a portion of a carcass is condemned, in spite of stockyard gossip and scandal, I believe that it is conscientiously destroyed. It would not be worth while to defy the law for such a trifle. But, on the other hand, no proper destructor establishment has been built.

It is obvious that the destructors should be placed in a far-off and isolated corner. Any condemned carcass should at once be removed well away from all the buildings where food is prepared. Nothing of the sort is done. They are kept under the same roof on the same floor where food is being prepared for human consumption. Indeed, worse than this, the diseased carcasses are brought nearest to the windows so that there may be a better light to examine them. But, on the other hand, such air as may gain admittance into the huge building from these windows passes round, over, and between these diseased carcasses before it can reach the moist meat that is being cut up and prepared at a short distance. When, finally, the carcass is taken to the destructor the opening of this tank, at least of the tank which I saw, is inside a large building in the floor and round it many people were working. *The place is dark, wet, and altogether in a most unsuitable condition for the handling of meat.* Nevertheless, not only is human food prepared here but diseased carcasses condemned as unfit for human food are dragged through the compartment. The lid of the destructor is removed within a few feet of meat that is to be eaten. The promiscuity of the two occupations, the examination and destruction of diseased carcasses and the preparing, the cutting up, or the washing of carcasses that are not diseased, is most disgusting and reprehensible. The best destructor I have seen is that of the municipality of Hamburg and it is situated not only outside the town but well away from the slaughter-house.[1] Formerly the destruction of diseased carcasses cost the town of Hamburg a considerable sum. But now the dry brown manure powder into which the carcasses are converted sells so well that there is a profit, even after paying all the working expenses. On the other hand, the interests of the public health are absolutely secured. The progressive energy of the inhabitants of Chicago has been the theme of many eulogies; but why are there no properly installed destructors for dealing with the many thousand diseased carcasses that are yearly condemned in the stockyards?

(To be continued.)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool School of Tropical Medicine: Visit of the Princess Christian and Mr. Joseph Chamberlain: Departure of the Fourteenth Expedition to the Tropics.

AN interesting address has been arranged by the School of Tropical Medicine to be delivered on Jan. 12th in the small concert room at St. George's Hall by Major Ronald Ross, C.B., late I.M.S., on the subject of the Progress of Tropical Medicine. The Princess Christian and the Right Hon. Joseph Chamberlain, M.P., have accepted the invitation of Sir Alfred Jones, K.C.M.G. (the chairman of the school) to be present on the occasion. Invitations have also been issued to the subscribers to the school. Mr. Chamberlain's presence at the meeting will be gratifying in view of the prominent part played by him in the foundation of the Schools of Tropical Medicine in London and Liverpool. The distinguished visitors will be the guests of the Earl of Derby, K.G., at Knowsley. The Earl and Countess and the Lord Mayor have also promised to attend the lecture. On Dec. 31st, 1904, the s.s. *Sobo* sailed from the Mersey for West Africa and amongst the passengers were Colonel G. M. J. Giles, I.M.S., late sanitary commissioner for the North-West Provinces of India, and Dr. R. E. M'Connell, a young Canadian, both being members of the fourteenth expedition sent out by the Liverpool School of Tropical Medicine for the further investigation of malaria and other tropical diseases. Just before the expedition sailed a message was received from Sir Alfred Jones wishing the members every success. Mr. W. Adamson, the president of the Royal Southern Hospital, and Mr. A. H. Milne, the secretary of the school, were present to bid Colonel Giles and Dr. M'Connell *bon voyage*, and they took their departure amid many good wishes from other friends.

Proposed Closing of Cellar Dwellings in the City: Extraordinary Result of a Town's Meeting.

The health and the parliamentary committees of the city council by unanimous votes had approved of the recommendation of the medical officer of health (Dr. E. W. Hope) to close (by degrees and with due regard to the rehousing of the dispossessed) 2500 out of 3000 cellar dwellings in the city which, in his opinion, were insanitary. The recommendation of both committees was subsequently endorsed by the city council by the large majority of 90 out of 98 members present. Under the Borough Funds Act the approval of a town's meeting was necessary before Parliamentary powers could be sought for the purpose. This and other beneficent sanitary measures were howled down with gibes and jeers by the town's meeting and sanitation in Liverpool received a disagreeable check. Clearly the Borough Funds Act needs amendment; *the decisions of the municipal representatives of the people to appeal to Parliament should not require the approval of a meeting easily packed by interested people.* The chairman of the health committee (Alderman Menlove), in an appeal to the meeting to ratify the vote of the ratepayers' representatives, said that he had a wide experience of cellar dwellings and many of them were not fit to keep a dog in. There was no doubt that many of them were most unwholesome and good dry dwellings must be provided if the rising generation was to grow up in health and strength. Dr. R. Caton and other city councillors also made strong appeals for the ratification of the measure but all to no purpose, the clause being lost by a large majority.

Death of Dr. James Armstrong.

Dr. James Armstrong, formerly of 84, Rodney-street, Liverpool, died suddenly at Plas Bennett, near Denbigh, on Dec. 26th, 1904. Dr. Armstrong retired from practice in Liverpool about two years ago owing to delicate health. He received his medical education at the University of Edinburgh where he graduated as M.B. in 1868 and in the same year obtained the diploma of the Royal College of Surgeons of Edinburgh. He was formerly physician to the Liverpool Infirmary for Children, resigning that post on his election as honorary physician to the Liverpool Lying-in Hospital. He had an extensive midwifery practice and made many contributions to the medical journals on the literature of that subject. He was of a quiet and gentle demeanour and made many friends among the profession in Liverpool where the intelligence of his death was received with manifestations of much sympathy. He was a widower and leaves a son and a daughter.

Jan. 10th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The Annual Dinner of the Past and Present Students of the School of Medicine.

THE annual dinner of the past and present students of the Leeds School of Medicine which was held recently was an event of unusual importance. Always a popular gathering, well attended, and affording to former students an opportunity of meeting again and renewing acquaintances, it derived an additional interest on this occasion as being the first dinner held since the granting of the University charter. During the last 20 years the Leeds School of Medicine has been officially known as the medical department of the Yorkshire College and it was a comfort to feel that the old term "School of Medicine" could again be used and with strict academic accuracy and not merely by custom as during these 20 years. A "school" of a university is a well-known term; a "school" of a college is at least unfamiliar as a term. Old Leeds men are never tired of saying with justifiable pride that the first year of the new University would have been the twenty-first of the medical department of the Yorkshire College and that it is the seventy-fourth of the Leeds School of Medicine. The chair was occupied by Dr J. B. Hellier and there were present 126 past and present students, including as guests the Vice-Chancellor, Dr. Bodington; the chairman of the Infirmary Board, Mr. Charles Lupton, who has taken such a keen interest in the welfare of the school and of the University as a whole; and representatives of the sister Universities of Manchester and Liverpool. Dr. Hellier proposed the toast of "The Past and Present Students" in a speech full of good sense and humour, and this was replied to by Mr. Coupland and Mr. Nicol. The toast of "The Staff," which was eloquently proposed by Mr. Reed, was appropriately responded to by Dr. E. F. Trevelyan, who has recently retired from the professorship of pathology, and by his successor, Professor A. S. F. Grünbaum, who received a most cordial welcome from all present. In replying to the toast of "The Guests," the Vice-Chancellor referred especially to the very cordial relationship which had always existed between the three colleges of the Victoria University. The relationship between the three sister universities would, he felt sure, be no less cordial, for the discussions which led to the disruption had always been conducted with mutual good feeling. He cordially welcomed the suggestion of the students' inter-university conference for the publication of a students' song-book on the lines already in force in the Scottish universities.

---

[1] THE LANCET, July 21st, 1894, p. 158.

National Physique.

In connexion with the question of national physique considerable interest attaches to some figures taken from the annual report of the Leeds recruiting dépôt and published in the *Yorkshire Evening Post*. During the 12 months just ended, while 589 recruits have been accepted for line regiments and 762 for the militia no fewer than 40 per cent. of rejections are registered. During the last three months of 1904 34 candidates who had satisfied the preliminary tests as to stature, chest measurement, &c., were rejected on account of bad teeth, defective eyesight, cardiac mischief, flat foot, and varicose veins. It is stated that the number of rejections on account of bad teeth is considerably higher than in most other large towns. If this is the case it is earnestly to be hoped that the unenviable notoriety of Leeds in this respect may in some measure be lessened by the establishment of the new dental department at the Leeds Public Dispensary, the arrangements for which have for long been matter of careful consideration by the board and which, it is believed, will soon be in full working order.

A Jewish Nursing Home.

An offer was made some time ago by Mr. Alderman Moses of Bradford to contribute £4000 towards the establishment of a Jewish nursing home or hospital in Leeds. The offer was qualified by some conditions which it was thought might hamper its usefulness and it has not as yet been accepted. It is felt by the influential members of the Jewish community that the General Infirmary makes adequate provision for the treatment both of in-patients and of out-patients. Special arrangements were, with the ready consent of the board, made some time ago to meet their views as to the preparation and the cooking of their food and Jewish patients are as freely admitted as others. It is, however, perhaps natural that in a city with a Jewish population of some 15,000 to 20,000 a special effort should be made from among their own body or by their co-religionists in less necessitous districts to provide for the needs of those who are either not ill enough to require admission to the medical wards or are not suffering from affections requiring surgical operation but who, on the other hand, may require good food and skilled nursing in addition to the treatment which they could obtain in the out-patient department.

Jan. 10th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Bristol Ambulance Service.

THE ambulance service in Bristol is now very well organised. During the past year more than 3000 persons received first aid from the members of the Bristol City and Marine Ambulance Corps, a body of volunteers which was established in 1900. Since October, 1903, the corps has been in possession of a fully equipped ambulance wagon which is at the disposal of any injured person free of charge and at any time of the day or night. It is used on an average about five times daily. The corps has lately purchased a brougham ambulance which is frequently used by patients who are able to pay for the service.

Swansea Sewerage Scheme.

The corporation of Swansea has once more met with a rebuff in its attempt to secure the efficient drainage of the lower portion of the borough. The scheme proposed by the corporation included the construction of an outfall sewer at Brynmill and provided for a septic tank for the treatment of the sewage before being discharged into Swansea Bay. The Local Government Board had sanctioned the proposal but the consent of the Board of Trade, which is also necessary, has been withheld in consequence of the report of its commissioner who held an inquiry into the question in September last. The corporation scheme was not supported with any enthusiasm either by the medical officer of health (Mr. Ebenezer Davies) or by the borough engineer.

Death of Dr. William Williams Morgan.

Dr. William Williams Morgan, who died at Newport (Mon.) on Jan. 7th, was one of the oldest medical practitioners in this country. He was born in Merthyr Tydfil in 1809 and after studying at the old Webb-street School and Guy's Hospital he took the diplomas of M.R.C.S. Eng. and L.S.A. in 1835. In 1862 he obtained the degree of M.D. at the University of St. Andrews. With the exception of the few months immediately succeeding his becoming qualified, when he was house surgeon to the Bury Dispensary, he has lived and practised entirely in Newport. For many years he was a member of the town council and was mayor of the borough in 1864. He was the senior borough magistrate and a prominent Freemason, having been admitted into the order so long ago as 1835. He was active in the formation of the two Newport lodges Silurian and Isca, having been the first Master of the latter. It is of interest to note that Dr. Morgan's father lived to the age of 92 years and that he himself was neither a non-smoker nor a total abstainer.

The Unfounded Charge against Dr. Arthur D. Griffiths.

A vote of sympathy with Dr. Arthur D. Griffiths of Bridgend was passed at a joint meeting of the Cardiff Medical Society and the Cardiff division of the British Medical Association held at Cardiff on Jan. 4th. It was also decided at the same meeting to invite subscriptions towards the heavy legal expenses incurred by Dr. Griffiths in successfully refuting the charges brought against him by a female patient, details of which have already appeared in THE LANCET.[1] Dr. A. P. Fiddian, the treasurer of the Cardiff Medical Society, has undertaken to receive the subscriptions.

Ptomaine Poisoning.

During the last week in December, 1904, three children living in one household in Nailsworth, Gloucestershire, died from what has since been shown to be ptomaine poisoning. They were of the ages respectively of six months, two years, and four years, and were all taken ill on the night of Dec. 23rd, the prominent symptoms being vomiting and diarrhœa. The youngest child died on Dec. 25th, the one aged two years on Dec. 27th, and the eldest three days later.

West Wales Sanatorium.

The county councils of Cardigan, Carmarthen, and Pembroke have not yet made any proposals to support the sanatorium for consumptives which is about to be erected for the inhabitants of the three counties. The West Wales branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis is now suggesting that the councils shall undertake the cost of administration, the buildings being handed over by the branch free of debt. It is stated that the amount to be contributed by the councils would be equal to a rate of ¼*d.* in the pound.

The Working of the Midwives Act in Cardiff.

It is considered in many quarters that the principal difficulty in the administration of the Midwives Act will arise in those cases where a nurse is compelled to call in a medical practitioner, for the payment of whose fee no provision has been made by the Act. In order to arrive at some equitable arrangement in the matter a conference was held on Dec. 9th, 1904, between representatives of the Cardiff Medical Society, the Cardiff division of the British Medical Association, and the Cardiff branch of the Queen's Nurses' Institute. At this conference certain suggestions were agreed upon and with slight alterations they were adopted at a joint meeting of the members of the medical society and the division held at Cardiff on Jan. 4th. The proposals are that where the Queen's nurse attends a patient a medical practitioner shall be engaged in every instance when the total weekly income from all sources exceeds 25*s.* in the case of a primipara, a deduction of 1*s.* 6*d.* per child being made in calculating the wage limit in subsequent attendances; the fee of the nurse is to be 10*s.* Where the total weekly income is between 25*s.* and 21*s.* the nurse's fee is to be 10*s.* or 5*s.* where a medical practitioner is engaged; where the income is below 21*s.* a week the nurse's fee is to be 7*s.* 6*d.* or 5*s.* where a medical practitioner is engaged, the destitute poor to be attended by the nurses free of charge. The nurses will be instructed to do all in their power to get the medical fee paid and will advise patients to put money by for this purpose; they will also explain carefully to patients at the time of engagement that a medical practitioner must of necessity be called in under very many contingencies and that it will therefore probably be to their interest to engage one beforehand and thus get the benefit of his services all through their illness. Wherever the total weekly income is under 21*s*. the patient will be advised to procure an order beforehand from the Poor-law authority, if the patient is unwilling to engage a medical practitioner, which order can be used if required. In cases of emergency the nurses are instructed to summon in the first instance the family medical attendant; where there is no family attendant and the probability of payment of a fee is remote the Poor-law medical officer is to be sent for; while in all cases of urgent necessity the nearest medical practitioner is to be called in. The scheme outlined above is to be tried for two years and the two medical societies will appoint at their next meetings representatives to sit as assessors upon the maternity committee of the Queen's Nurses' Institute and to give the committee the benefit of their advice.

[1] THE LANCET, Dec. 17th, 1904, p. 1733.

Jan. 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Visit of Professor G. Sims Woodhead to Belfast.

Professor G. Sims Woodhead of Cambridge visited Belfast last week on the invitation of the North of Ireland branch of the British Medical Temperance Association and gave three addresses. On Thursday afternoon in one of the large halls he delivered, by special request, the Lees-Rapper Lecture on Alcohol and Public Health. The Lord Mayor of Belfast (Sir Otto Jaffe) presided and there was a very large attendance. At the conclusion of the lecture Professor Woodhead was awarded a warm vote of thanks, proposed by Dr. Charles Kevin (president of the North of Ireland branch of the British Medical Temperance Association), and seconded by Professor J. W. Byers. In the evening, at the Ulster Medical Society, Professor Woodhead opened a discussion on the subject of Alcohol as a Protoplasmic Poison. In doing so he referred to the great interest that was now taken in the action of alcohol on the tissues both in disease and in health. In what he had to say he should try to be as moderate as possible and he might state at the outset that convinced as he was on many points there were many on which they would no doubt disagree. However, they were there to get at the root of the matter and not to agree except where they could do so with a good conscience. He first referred to the many experiments that had been carried out with various dilutions on animals of many species and on plants. He then gave a short account of the action of alcohol in different dilutions upon phosphorescent bacilli, taking this organism as a useful type; special stress was laid upon the fact that long before the bacillus was killed its functional activity as a light producer was interfered with. The results of these experiments could easily be recorded as the phosphorescence was sufficiently powerful to allow of photographs being obtained. This action of alcohol upon naked protoplasm had often been referred to as beside the mark, but they must remember that it had been maintained that alcohol was oxidised in the body and in the tissues and if it was oxidised there it must get there in however weak dilutions. The action of alcohol in the production of fatty infiltration and degeneration was then referred to and its action upon the heart, liver, and kidney, especially in so far as we had evidence of any interference with the metabolic oxidation associated with its presence in the tissues. He maintained that the heart was one of the organs on which alcohol exerted some of its most disastrous effects and he for one considered that the use of alcohol in heart cases was far more frequently contra-indicated than indicated and he quoted several authorities in support of his contention. He pointed out that although we had evidence of changes in the nerve cells which appeared to be the direct result of the action of alcohol on the nerve cells and their processes, we too often left out of account the fact that the lower tissues, connective and elastic, were in all probability affected at a much earlier stage than was generally accepted. What was seen in the liver and sometimes in the kidney on an extensive scale might be, and in all probability was, reproduced in a minor degree and perhaps more slowly in the delicate cells of endothelial and connective tissue type in walls of blood-vessels of various sizes. Some of these changes took the form of proliferation and connective tissue formation, usually associated with the degeneration and later calcification of the muscular coat. These changes were due in part to the presence of alcohol which interfered with both anabolism and katabolism, and in part to the storage of waste products which should under ordinary conditions be got rid of. Professor Woodhead then referred to the experiments made on the production of immunity against rabies, tetanus, and anthrax and on the action of the diphtheria bacillus and its poison and the tubercle bacillus upon alcoholised and non-alcoholised animals. He spoke of the action of alcohol as a "retarder" in the process of the production of a condition of immunity or insusceptibility and maintained that any substance that exerted such extraordinary effects should be used with the greatest care and only with the object of obtaining certain definite effects and after a careful balancing of the profit and loss accounts. In the discussion which followed Professor Byers, Professor J. A. Lindsay, Dr. Kevin, Professor T. H. Milroy, Dr. J. Campbell, Dr. A. G. Robb, Mr. A. B. Mitchell, and the President (Dr. W. Calwell) took part. After Professor Woodhead had replied a special vote of thanks was accorded to him on the motion of Professor J. Symington, F.R.S., seconded by Dr. Campbell. On the evening of Friday, Jan. 6th, Professor Woodhead delivered a very interesting address on the Reasons why he was an Abstainer from Alcohol in the Students' Union, Queen's College, Belfast, before the Belfast Medical Students' Association. Dr. J. Lowry, the President, occupied the chair and there was a very large attendance. At the conclusion of the address Professor Milroy proposed, and Professor J. Park, M.A., D.Litt., seconded, a vote of thanks to Professor Woodhead, which was cordially supported by the Lord Mayor of Belfast. Professor Woodhead's visit to Belfast has been a marked success. His extreme fairness in putting forward his views, his evident sincerity, his scientific method of dealing with the questions which he discussed before audiences with very diverse opinions on the subject, and above all his total absence of dogmatism, charmed everyone with whom he was brought in contact, whether they accepted his conclusions or not.

Fractures of the Humerus treated with the Heitz-Boyer Apparatus.

AT the meeting of the Society of Surgery held on Dec. 8th, [illegible]

ratus. One patient had had a T-shaped fracture of the lower end of the humerus extending into the joint and the other a fracture of the upper end of the bone with considerable over-riding of the lower fragment. In both cases Hennequin's apparatus, although applied immediately after the injury, had only brought about partial reduction, as was evident by x ray photographs. The application of the Heitz-Boyer apparatus, however, brought about perfect reduction and the bone united in excellent position. The functional use of the limb was perfectly restored in both patients. M. Quénu and M. Broca both gave evidence as to the admirable results which they had obtained with the apparatus in question. M. Lucas-Championnière, however, said that perfect reduction was by no means a *sine quâ n*[illegible]ure good functional results. For [illegible] to bring forward plenty of pati[illegible]dults, in whom simple massage unaccompanied by the use of any apparatus had brought about just as good results as in the patients alluded to by M. Schwartz and M. Quénu.

Graefe's Coin-catcher and Foreign Bodies in the Œsophagus.

At the meeting of the Society of Surgery held on Dec. 21st M. Sebileau showed the œsophagus of a child, aged two and a half years, which exhibited two perforations caused by attempts to extract a sou by means of Graefe's coin-catcher (*panier*). On account of this misfortune a discussion arose as to the advisability of giving up the use of the coin-catcher. M. Félizet did not think that it should be given up but that it was necessary for the operator to be well acquainted with the instrument. He used a sponge mounted on a handle at the same time as the catcher. The sponge dilated the œsophagus and the catcher brought up the foreign body. M. Broca was of the same opinion. He thought that the catcher was an excellent instrument but it should not be employed except for coins. M. Kirmisson said that he considered it preferable to employ a hook in place of the catcher and the hook had given excellent results in his hands and in those of M. Faure. M. Jalaguier sometimes used the catcher and sometimes the hook. Occasionally neither instrument succeeded and when the coin lay near the cardiac end of the œsophagus, as was the case in a child, aged seven years, who had swallowed a sou, and who was under the care of M. Segond, a gastrotomy should be performed. At the following meeting of the society M. Kirmisson reverted to the subject and uttered a protest against the ideas of certain surgeons who argued that they had (in cases of extraction of coins through the mouth) obtained equally good results whatever the instrument they used. His own opinion was that the hook, especially in very young children, had one enormous advantage over the catcher in that its diameter was at least half that of the catcher and this permitted it to pass easily in cases where the catcher containing the coin was likely to engage in the walls of the œsophagus with fatal results.

A Matter of Public Health.

The Council of Hygiene of the Seine has approved an order of the Prefect of Police forbidding the throwing on the pavement of sweetmeats and other comfits in view of the danger to the health of children who may eat such comfits. They are found scattered on the pavement after certain family parties (*cérémonies de famille*). These sugarplums are naturally always soiled by mud or dust and so they are quite capable of serving as vehicles for the germs of transmissible diseases, more especially those of tubercle. The circular of regulations sent out to police commissaries and *officiers de paix* instructs them to deliver a verbal summons to any offender who shall contravene the Prefect's order.

The Escape of Milk by the Ear in a Child suffering from Congenital Deficiency of the Soft Palate.

At the meeting of the Society of Pediatrics held on Dec. 20th, 1904, M. Variot showed a female child, aged three months, suffering from cleft of the soft palate. Nevertheless the child, despite the fact that milk regurgitated from time to time through the nose, was able to take nourishment in a satisfactory manner, but a fortnight before the child was exhibited the mother noticed that whenever she nursed the child a certain quantity of milk escaped through the right ear. On examination there was found to be complete perforation of the right tympanic membrane and M. Le Marc-Hadour, who made an otoscopic examination, thought that the perforation had followed an otitis and was not due to any congenital malformation of the tympanum.

Chloride of Sodium and Dropsy.

THE effects of removing chloride of sodium from the diet, to the importance of which in pathological conditions associated with anasarca, &c., attention has been called by Widal and others, have lately been tested by several Italian clinicians. Massalonga and Zambelli, in a communication read before the recent Congress of Internal Medicine confirm what these authors state—namely, that the retention of chloride of sodium has a preponderating share in the genesis of œdema, although it does not always stand in any definite relation to the œdema itself. The most important of the effects produced by it is upon nephritic subjects in whom a few grammes of salt suffice to provoke or to augment œdema, whilst the removal of it from the diet causes the œdema to diminish or to disappear altogether. A suitable diet poor in chloride of sodium was enough in almost every case to better the general condition of the patient, to reduce albuminuria and to stimulate diuresis. But also in dropsy of cardiac origin a salt-free diet is very often of itself sufficient to diminish the œdema, re-establishing the function of the heart and facilitating the action of cardiac tonics where these had not previously proved effectual. Considerable improvement in the grave state of a patient may thus be brought about. In like manner the ascites of hepatic cirrhosis may be reduced with or without diuretics by the same means and even in tuberculous effusions into the peritoneal cavity and sero-fibrinous exudations of the pleura it sometimes, though less frequently, proves of signal service, especially where no fever is present. Cioffi has obtained similar results but enjoins care in prolonging beyond a certain point the salt-free diet as liable to cause grave changes in the kidneys. Experimenting on healthy guinea-pigs he found that after only 24 hours of salt-free diet there appeared in the urine albumin and tube casts in great numbers and that these immediately disappeared when ordinary diet was resumed. On the other hand, by injecting into the veins a small amount of salt solution he was also able to produce a similar result, thus proving that an excess of salt has the same injurious effect as the withdrawal of it, the convoluted tubules in both cases showing almost identical alterations.

The Improvement in the Sanitary Condition of Italy.

The following table is compiled from the "Annuario di Statistica" for 1904 and shows the number of deaths which took place in Italy from infectious diseases in each year from 1887 to 1902 inclusive, only those infectious diseases, however, being selected the notification of which is compulsory—viz., small-pox and varioloid, measles, scarlet fever, diphtheria and croup, typhus and typhoid fevers, puerperal fever, pulmonary tuberculosis, malaria, syphilis, rabies, and malignant pustule:—

Year.	Deaths.	Rate per 1000 inhabitants.	General death-rate per 1000.
1887	170,628	5·78	27·99
1888	152,088	5·12	27·51
1889	129,918	4·34	25·57
1890	116,399	3·86	26·32
1891	119,140	3·92	26·11
1892	105,096	3·44	26·18
1893	105,160	3·42	25·16
1894	96,865	3·33	24·93
1895	97,920	3·14	25·05
1896	93,977	2·99	24·06
1897	82,422	2·61	21·93
1898	81,455	2·56	22 94
1899	84,077	2·62	21·89
1900	90,280	2 80	23 77
1901	80,477	2·48	21·95
1902	76,071	2·32	22·15

In 1902 there were thus 94,557 fewer deaths from that class of disease than in 1887, and reckoning the morbidity at 100 patients for every 12 deaths there would be nearly 800,000 fewer patients ill in the former year than in the latter. If 30 days be allowed for an average illness and convalescence, and 1*s.* 8*d.* per day for the cost of living, then a saving will have been effected during 1902 as compared with 1887 of nearly £2,000,000, in addition to the amount represented by the 94,557 persons who have presumably been rescued from death. The economic value alone of this reduction in the amount of illness and mortality from infectious diseases in Italy is therefore very high. During these years the population, which in 1887 was 29,510,284, increased to 32,704,166 in 1902, whilst, as will be seen from the table, the death-rate per 1000 inhabitants diminished during the same period from 27·99 to 22·15.

Medical Men in the Italian Chamber of Deputies.

In the Parliament which was recently elected and is now sitting there are 22 medical deputies, representing wards in 18 provinces of Italy. The list includes several well-known names, such as Baccelli and Santini (for Rome), Celli (for Cagli), Sanarelli (for Bibbieno), and Rummo (for Benevento).

All but three (Colajanni, Pantano, and Santini) are men in active practice or who occupy university chairs

Vital Statistics of St John New Brunswick

THERE were 751 deaths in St John, New Brunswick during the year ending Oct 31st 1904 as compared with 777 in the previous year Tuberculosis was responsible for 108 of the number as against 89 cases in 1903 Of the total number who died 376 were males and 375 were females 365 were single and 386 were married The number of deaths at some periods of age was as follows under one year 133 from 70 to 80 years 96, from 60 to 70 years 90 from 50 to 60 years 69, from 40 to 50 years 56, and from 30 to 40 years 46 The report of contagious diseases for the year numbered 246 cases the details being as follows diphtheria 100 cases with 11 deaths, scarlet fever 58 cases with two deaths, measles 67 cases with one death, typhoid fever 20 cases with six deaths, and small pox, one case, with no mortality

Vaccination in Montreal

The medical health officer of Montreal in his report states that of all of the cases of small pox occurring in that city in 1903 not even one person suffered from the disease who had been vaccinated during the past five years One year ago when the official vaccinators were visiting all the schools in order to vaccinate unvaccinated children over 1000 refused to attend school because they had to submit to vaccination This year there is scarcely any opposition On Jan 1st 1903 there were five patients in the Montreal Small pox Hospital and 90 cases were admitted during the year The deaths numbered two and one remained in the hospital at the end of the year The males included 41 adults and 11 minors, the females included 26 adults and 12 minors As already stated there were no cases which had been vaccinated within the past five years but there were 13 cases which had been vaccinated some years ago and there were 77 cases unvaccinated

By laws against Spitting in Montreal

With a view to prevent the dissemination of tubercle bacilli the city council of Montreal has decided to pass the following by law prohibiting spitting in public places "No person shall spit upon the floor of any railway car, street car or other public conveyance or upon the floor of any theatre public building church opera house, music hall or hall used for public meetings railway or steamboat stations, or waiting rooms or other public hall, building room or place or upon any platform surrounding in front of or in the immediate vicinity of any such place or upon any side walk or any covered way within the limits of the city of Montreal

Alexandra Hospital, Montreal

The delay in the construction of the Alexandra Hospital for Contagious Diseases Montreal was the subject of a conference recently between the directors of the institution and the civic hygienic committee The conference was brought about owing to the prevalence of diphtheria in the city and to the fact that the directors of the hospital had undertaken that accommodation should be available on Jan 1st 1905 The delay has been occasioned by the legislature prohibiting the hospital authorities from building on the site selected Another site was procured at a cost of $90 000, but then the directors thought it wise to proceed cautiously until they had sufficient funds in hand They have now $40 000 and the hospital will be proceeded with at once and by September next will be ready for the accommodation of patients Montreal had 87 cases of diphtheria during last November

NEW YORK

(FROM OUR OWN CORRESPONDENT)

The New York Society of Medical Jurisprudence discards the Title of Doctor

THE New York Society of Medical Jurisprudence held its 149th annual meeting at the New York Academy of Medicine on Dec 12th 1904 A motion was proposed and carried unanimously that in all literature of the society the title of physician should henceforth be employed instead of doctor There can be no doubt that the title 'doctor is used far too indiscriminately in the United States and the move on the part of the Society of Medical Jurisprudence is wholly justified by the facts of the case

Dietary in Bellevue Hospital New York

The feeding of the patients in the majority of hospitals is not altogether satisfactory The diet at Bellevue Hospital, New York has for some time been subjected to adverse criticism and it has recently been decided to make a change in this respect A new kitchen system has been installed and is under the direction of a qualified and scientific cook assisted by a competent staff Special dietaries have been introduced for special diseases and in every way, so far as dieting is concerned the interests of the patients will be the first consideration

Proportion of the Sexes in the United States

The United States Census Bureau has just made public a study and analysis of the proportion of the sexes in the United States compiled by Professor W F Willcox of Cornell University and based upon the figures of the twelfth census From these figures the fact is gathered that in the United States there are 1 638 321 more males than females but the proportionate excess of males is less at present than it appeared in the previous census Professor Willcox says The divisions of the United States with the smallest proportion of males are the District of Columbia (47 4 per cent.), Massachusetts (48 7 per cent) and Rhode Island (49 1 per cent) those with the largest are Wyoming (62 9 per cent) and Montana (61 6 per cent) American cities as a rule have more females than male In the 1861 cities, each having in 1900 at least 2500 inhabitants there were 201 959 more females than males In all races and in all parts of the United States there has been a decided increase since 1890 in the proportion of females attending school The death rate of males in the registration area of the United States in 1900 was 19 per 1000 and that of females 16 6 per 1000, the former having a death rate higher by about one seventh than the latter In the 346 registration cities of the United States the death-rate of males was 20·0 and that of females 17·2 per 1000, the male-rate exceeding the female by one-sixth."

Meeting of the American Association for the Advancement of Science.

The fifty-fourth Convocation of the American Association for the Advancement of Science met in Philadelphia on Dec. 27th. All the sessions were held in the buildings of the University of Pennsylvania. Professor Carroll D. Wright retired from the presidency of the association and was succeeded by Professor W. G. Farlow of Harvard. The newly elected vice-presidents are: Professor Alexander Ziwet, University of Michigan; Professor W. F. Magie, Princeton; Professor L. P. Kinnicutt, Worcester Polytechnic Institute; Professor D. S. Jacobus, Stevens Institute; Professor Eugene A. Smith, University of Alabama; Professor C. Hart Merriam, Department of Agriculture, Washington; Professor B. L. Robinson, Harvard; Dr. Walter Hough, National Museum, Washington; Professor M. A. Knapp, chairman of the Inter-State Commerce Commission; and Professor H. P. Bowditch, Harvard. Among papers of interest read at the meeting was one by Dr. Spitzka of Columbia University on different types of the brain. Dr. Spitzka said that judging from the present indications of the formation of the brain in the members of an American family of the Aryan race, the conditions governing the population of the United States seem to have been peculiarly advantageous to the preservation and restoration of the best types, characterised by greater energy, motility, and culture. We may, therefore, thinks Dr. Spitzka, expect to find bigger and better brains in America eventually. Referring to the brains of criminals he ridiculed the idea that the criminal brain was of a decidedly different type from that of an ordinary individual. Many criminals, he said, show not a single anomaly in their physical or mental conformation, while many persons with marked evidences of morphological aberration have never exhibited a criminal tendency. The retiring vice-president of the Chemical Section, Dr. Wilder S. Bancroft, in his address made some remarks on the possibility of the transmutation of elements. He said that the fact that transmutation of the elements has never been observed does not prove that none has taken place. If Lockyer's conclusions as to the state of things in the sun were accepted many of the elements could undoubtedly be broken up if they could be exposed long enough to 6000° Centigrade.

Jan. 4th.

Obituary.

WILLIAM TURNER, M.R.C.S. ENG., L.S.A.

THE recent death of Mr. William Turner of Poole, Dorset, sadly illustrates some of the risks of medical practice. The deceased who was in his sixtieth year, while performing an operation at the Cornelia Hospital, Poole, on Oct. 25th, pricked the first finger of his left hand with the needle which he was using. The finger was immediately washed with an antiseptic solution, but to no purpose, as a medical friend was asked to see him on Oct. 27th on account of the painful state of the finger and arm and the illness continued with various exacerbations and remissions until it terminated fatally on Nov. 25th. At an inquest which was held on Nov. 27th the verdict was to the effect that death was due to blood poisoning and much sympathy for the family was expressed by both the coroner and the jury. Mr. Turner's professional education was received at Guy's Hospital and in 1867 he became qualified as M.R.C.S. Eng. and L.S.A. Soon afterwards he settled in Poole and eventually acquired the practice of the late Mr. Lacey of that town. In 1886 he was appointed a borough magistrate. Among various local positions which he held may be mentioned that of medical officer and public vaccinator of the first district and the workhouse of the Poole union, medical officer of the industrial school, and honorary surgeon of the Cornelia Hospital. He also acted as deputy coroner a few years ago. Mr. Turner took a great interest in Freemasonry. He was a Past Master of the Amity Lodge No. 137 and had held high office in the Provincial Grand Lodge of Dorsetshire. He was also a prominent figure in yachting circles and in former years his yacht gained several prizes; at the time of his death he was chairman of the sailing committee of the Yacht Club and was last year elected chairman of the regatta committee. For several years he was president of the Poole Natural History Club and was also associated with the Dorset Field Club. He has left a widow and a family consisting of five daughters and three sons. The funeral took place on Nov. 29th in Poole Cemetery.

THOMAS MORLEY ROOKE, M.D. LOND.

THE death occurred recently at Bournemouth of Dr. Thomas Morley Rooke. He had been much indisposed for some time and succumbed 24 hours after an operation which was undertaken in order if possible to save his life. Born at York in 1826 he entered as a student at Guy's Hospital, where his remarkable diligence was speedily recognised, and at the University of London, where he graduated as M.B. in 1852, carrying off the "blue riband" of the medical examination world by gaining the gold medal in medicine and the University scholarship. He took the degree of M.D. a year later. Always a hard worker, without adequate holiday, he started practice in London, but indifferent health, followed by hæmorrhage from the lungs, made it advisable for him to take a long sea voyage. After a year's rest he returned quite well and proved himself by his subsequent long life a good example of permanent recovery from a tuberculous lesion. He then commenced practice at Scarborough but an unfortunate *contretemps* made him beat a hasty retreat from this place where there was then thriving a certain "Dr. Rooke," proprietor of much-advertised quack nostrums and editor of a pamphlet called the "Anti-Lancet." The confusion entailed by the presence of two "Dr. Rookes" caused Dr. Morley Rooke so much annoyance that he was glad to exchange for another sphere and he chose Cheltenham. All his life, however, "Dr. Rooke's Anti-Lancet" was a never-failing source of joking with him. He spent 37 years in practice at Cheltenham where he held the office of President of the Gloucestershire branch of the British Medical Association and was consulting physician to the Cobourg Dispensary for Diseases of Women and Children and physician to the Derbyshire General Infirmary. He always kept himself abreast of the times in medical and scientific matters but it was as the best type of family physician that his memory will long be revered in Cheltenham. Though with a constitution never very robust his thoughts were always concentrated on his patients. Ten years ago the state of his health made him relinquish his practice and retire to Bournemouth, where he resided until his death. There he devoted his time and energy in relieving the sufferings of the poor and acted for a time as honorary secretary to the Charity Organisation Society. He was the type of the upright Christian man who delighted in doing good works not for his own soul's sake but for the good and pleasure that it gave to others. As a medical man in Bournemouth writes: "In these latter days his profession can ill spare one whose bearing so well represented the best type of a courtly English gentleman."

ALEXANDER LOCKHART GILLESPIE, M.D. EDIN., F.R.C.P. EDIN., F.R.S. EDIN.

BY the death of Dr. Alexander Lockhart Gillespie Edinburgh has lost one of its younger physicians and one of whom much might have been expected. He died suddenly from heart failure on Dec. 25th, 1904. He was a graduate in medicine of Edinburgh of 1888 and took the doctorate of medicine in 1892, receiving a gold medal for his thesis. In the same year he became a Fellow of the Royal College of Physicians of Edinburgh. He was a member of numerous medical and scientific societies. He came of a medical family, both his father and grandfather having been prominent men in their day. He was himself a man of great ability, of remarkable power of work, and of marked versatility He was the author of a book on "The Natural History of Digestion" and of another on "Modern Gastric Methods." He had contributed many articles to medical societies and to the medical press. In the estimation of his brethren in Edinburgh he held a foremost place amongst the medical song writers of the younger generation. At the time of his death he held the post of medical registrar at the Edinburgh Royal Infirmary. His wife predeceased him and he has left three children.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. Alexander Bobroff, professor of surgery in the University of Moscow. He was the author of various surgical works.—Professor Nicolas Sklifosovski, surgeon to the Military Medical Academy in St. Petersburg, who was president of the Organising Committee of the International Congress of Medicine at Moscow.—Dr. P. Q. Brondegeest, lecturer in pharmacology in the University of Utrecht.—Dr. Lecorché, formerly medical officer to the Paris hospitals.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination held recently the following candidates passed in the subjects indicated:—

PART I.

Biology.—A. J. V. Matthews, St. Mary's Hospital; V. P. Norman, London Hospital; H. H. Smith, Royal Free Hospital, and J. B. [illegible] Packa- [illegible]

PART II.

[illegible] Ford, [illegible] C C [illegible] spital, [illegible] spital, [illegible] spital; [illegible]

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Erich Abderhalden has been recognised as *privat-docent* of Physiological Chemistry and Dr. Helbron as *privat-docent* of Ophthalmology.—*Bonn:* Dr. Otto Burchardt has been recognised as *privat-docent* of Laryngology and Otology.—*Breslau:* Dr. Paul Jansen, *privat-docent* of Physiology, has been granted the title of Professor.—*Giessen:* Dr. [illegible] recognised as *privat-docent* [illegible] Pathological Anatomy.—*Je* [illegible] has been recognised as *privat-docent* of Surgery.—*Kazan:* Dr. N. Guerken has been promoted to the Professorship of External Pathology. Dr. Levchatkin has been recognised as *privat-docent* of Psychiatry.—*Kiel:* Dr Karl Holzapfel, *privat-docent* of Gynæcology, has been granted the title of Professor.—*Marburg:* Dr. O. Loewi, Director of the Pharmacological Institute, has been granted the title of Professor; Dr. A. Riedlander, First Assistant in the University Gynæcological Clinic, has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Naples:* Dr. Giovanni Galli has been recognised as *privat-docent* of Internal Pathology.—*Pavia:* Dr. Maurizio Ascoli has been recognised as *privat-docent* of Internal Pathology.—*Prague (German University):* Dr. Theodor Petrina, *privat-docent* of Medicine, and Dr. Enoch H. Kisch, *privat-docent* of Balneology, have been promoted to Extraordinary Professorships; Dr. Alfred Kohn has been [illegible] *St. Peters-* [illegible] Chaqovets [illegible] —*Vienna:* Dr. Johann Fein has been recognised as *privat-docent* of Laryngology and Rhinology.—*Zurich:* Dr. Oskar Wild has been recognised as *privat-docent* of Laryngology and Rhinology.

UNIVERSITY OF CAMBRIDGE.—The examiners in State Medicine for the ensuing year are Mr. Purvis, St. John's, Dr. G. H. F. Nuttall, Christ's, Dr. J. F. W. Tatham, Dr. J. Lane Notter, and Dr. R. D. Sweeting.—The examiners in Tropical Medicine and Hygiene are Dr. Nuttall, Sir Patrick Manson, and Professor Ronald Ross.—Mr. R. P. Gregory, demonstrator of botany, has been elected to a Fellowship at St. John's College.—Mr. A. E. Shipley, F.R.S., Christ's, has been elected a member of the Council of the Senate.—Mr. J. C. Willis, Caius, director of the Botanic Gardens, Peradeniya, has been approved for the degree of Doctor of Science.

ROYAL CORNWALL INFIRMARY.—Sir Robert Harvey of Trenowth, Cornwall, has given £1000 to the Royal Cornwall Infirmary, Truro, for the purpose of endowing a bed as a memorial to his wife, the late Lady Harvey.

ADVANCED LECTURES ON PHYSIOLOGY AT UNIVERSITY COLLEGE, LONDON.—A course of ten lectures on Enzymes will be given by Mr. W. M. Bayliss, F.R.S., in the Physiological Theatre, University College, London, on Wednesdays, at 5 P.M., commencing on Wednesday next, Jan. 18th. This course is a continuation of that given in 1904 and in it a selection of typical enzymes, such as invertase, lactase, pepsin, trypsin, lipase, and oxydase, will be discussed. These lectures are open to all internal students of the University of London and also to medical practitioners on presentation of their cards.

METROPOLITAN HOSPITAL SUNDAY FUND.—A meeting of the council was held at the Mansion House on Tuesday, Jan. 10th, the Lord Mayor being in the chair. The committee for general purposes, consisting of the President, Vice-President, and 19 members, was reappointed. In the committee of distribution there were two vacancies, Mr. Herman Hoskier having died and Captain Cundy having retired. In their places the council elected Mr. Felix Schuster and Mr. George Herring, who has during the last five years contributed £65,000 to the Fund. Mr. R. D. Martin, M.P., and Mr. John S. Gilliat were reappointed honorary secretaries, Mr. Charles Chester, honorary solicitor, and Messrs. W. H. Pannell and Co., honorary auditors.

LITERARY INTELLIGENCE.—Messrs. Longmans and Co. have in the press a collection of papers communicated to the Academy [illegible] the subject of t[illegible] book. The work, [illegible] structions for the construction of phosphorescent screens, has been translated into English by M. J. Garcin and the translation has been revised by Professor A. W. Reinold. It is announced that many of Professor Blondlot's observations are of a simple character and may be repeated without special apparatus and that a small phosphorescent screen, suitable for repeating some of the experiments, is attached to the book. This work should be of great interest as the existence of the "n" rays has been denied by a large number of scientific men in this country and on the continent and in the October and November numbers of the *Revue Scientifique* this difference of opinion has been expressed and Professor Blondlot himself has taken a part in the controversy. An interesting synopsis of the situation revealed by the *Revue Scientifique* appeared in the *Literary Digest* published in New York on Dec. 17t[illegible] shortly publish a book by [illegible] L.R.C.P. Lond., consulting [illegible] firmary, entitled "Religion and Health; their Mutual Relationship and Influence."

DONATIONS AND BEQUESTS.—By the will of Mr. S. Charrington, M.P., £500 are bequeathed to the East London Hospital for Children and £500 to the Victoria Park Hospital for Children and £500 yearly for three years to the London Hospital.—Under the will of Mr. Edwin Hunt the West Bromwich Hospital receives £500 and the Guest Hospital at Dudley a like sum.—Dr. Bentham Casaubon Chandler has bequeathed £300 to the National Hospital for the Paralysed and Epileptic and £300 to the Home for Incurables, Clapham.—By the will of Mrs. Ann Jameson £300 will be equally divided among the [illegible] ick Hospital, the Sunder- [illegible] Blind Institution, and the [illegible] Subject to certain legacies [illegible] which has been valued at £4575 2*s.* 4*d.* gross, and £3377 12*s.* 7*d.* net, is left in trust as to tw[illegible] Royal Infirmary and one-third [illegible] —Mr. John Wishart Lyell [illegible] llesex Hospital, to be [illegible] income paid annually to t[illegible] the event of the scholarship passing for a year, the income is to be applied for the general purposes of the hospital.—The Rev. A. Watson has bequeathed £250 to the Radcliffe Infirmary at Oxford; £200 to the Royal Free

Hospital, Gray's-inn-road; £150 to the Kidderminster Infirmary and Children's Hospital; £100 to the Hospital for Sick Children, Great Ormond-street; and £50 to the Wimbledon Cottage Hospital.—Mrs. Emma Elizabeth Temple has under her will bequeathed £2000 to Charing Cross Hospital and like sums to the West London Hospital, Hammersmith, to St. George's Hospital, and to King's College Hospital.

SUPERANNUATION ALLOWANCE —At a meeting of the Helston (Cornwall) board of guardians held on Dec. 31st, 1904, it was unanimously resolved to grant a superannuation allowance of £33 per annum to Mr. W. Wearne, who had recently resigned his appointment of district medical officer after 33 years' service.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—The committee of this hospital has decided to limit to 65 the number of new cases which can be seen in the out-patient department on any one day. This reform, which is taking effect from Jan. 2nd, has been made in response to representations from the medical staff, who pointed out that on certain days it was no uncommon thing for as many as 40, 50, or 60 new cases to be referred for treatment to a single member of the staff and that in such circumstances it was impossible to give proper attention to each case. The necessity for the new regulation has arisen, we are informed, not so much from the excessive number of out-patients applying for treatment in the 12 months as from the fact that the large majority present themselves on Mondays and Tuesdays, thereby crowding the out-patient department and making satisfactory work impossible on those days. The object aimed at is not the diminution of the number of out-patients as a whole but their more even distribution over the week. Patients coming with a recommendation from a medical man will always be seen, notwithstanding the new regulation, while care will also be taken that no hardship is inflicted on patients coming from a considerable distance.

UNIVERSITY OF LEEDS.—The time tables for the March and July examinations in the Faculty of Medicine have been issued. Written examinations begin on March 20th and July 10th and the practical and oral examinations in the case of each follow on the written one. The following appointments to external examinerships have been made by the council:—Medicine: G. Newton Pitt, M.D. Cantab., F.R.C.P. Lond., lecturer on pathology, Guy's Hospital. Surgery: Albert Carless, M.B., M.S. Lond., F.R.C.S. Eng., professor of surgery at King's College, London. Pathology: William Bulloch, M.D. Aberd., lecturer on pathology at London Hospital. Midwifery and Gynæcology: Peter Horrocks, M.D. Lond., F.R.C.P. Lond., obstetric physician to Guy's Hospital. Mental Diseases: G. Newton Pitt, M.D. Cantab., F.R.C.P. Lond. Medical Jurisprudence: Sir Thomas Stevenson, M.D. Lond., F.R.C.P. Lond., senior scientific analyst to the Home Office. Public Health: J. Lane Notter, M.D. Dub., late professor of military hygiene, Netley. Materia Medica: Francis Warner, M.D. Lond., F.R.C.P. Lond., F.R.C.S. Eng., lecturer in the London Hospital Medical College. Anatomy: George Dancer Thane, M.R.C.S. Eng., professor of anatomy at University College, London. Physiology: J. S. Edkins, M.B. Cantab., lecturer on physiology at St. Bartholomew's Hospital. These appointments have been made in accordance with the following regulation—viz., external examiners are appointed at first for one year only but they are eligible for re-election for a further period of two years. They are recommended by the Senate for election by the council in any case in which the board of the faculty concerned shall present a recommendation passed by the board *nemine contradicente* in favour of the appointment of a particular examiner, but in other cases after an advertisement for such examiner shall have appeared in selected newspapers. To meet the immediate requirements of the pathological department a sum of £294 has been placed by the council at the disposal of Professor A. S. F. Grünbaum.

BOOKS, ETC., RECEIVED.

N.B—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A PECULIAR FEATURE OF THE RECENT FOG.

To the Editors of THE LANCET.

SIRS,—*Re* "A Peculiar Feature of the Recent Fog" in THE LANCET of Jan. 7th, p. 43, I beg to state that during the last fog I observed the same feature in the flames of the gas stoves in our office in the City as well as in those of the kitchen gas stove in my residence in Balham. The Bunsen flames showed a most intense yellow colour, the intensity varying during the day. Therefore I do not consider that the phenomenon arose from any mechanical scattering of sodium salts but it seems more likely that the presence of small particles of sea-water caused it.

I may mention, as possibly bearing on this subject, that once I tried to ascertain the quantity of sea salt suspended in the air on the German Isle of Sylt. The air showed that distinct "smell and taste of sea salt" and the spectroscope proved distinctly the presence of sodium which turned the blue Bunsen flame into yellow, but my then very simple means of analysis failed entirely to prove the presence of weighable parts of NaCl.

I am, Sirs, yours faithfully,
Upper Thames-street, E.C., Jan. 7th, 1905. E. FERNER.

To the Editors of THE LANCET.

SIRS,—Might not the yellow colouration of the flames of the gas in your offices be due to the fact that during the fog there was frost and that many of the cleansing authorities in London used salt in the streets to break up the ice which had formed on the roads? The atmosphere must have been impregnated with saline particles which would later, when dissipated, be brought into contact with the flame.

I am, Sirs, yours faithfully,
Trafalgar-square, W.C., Jan. 7th, 1905. A. G. BATEMAN.

THE EFFECT OF SNUFF ON THE ACTION OF THE HEART.

To the Editors of THE LANCET.

SIRS,—Can any of your readers refer me to any literature on the above subject or give me any trustworthy information as to what (if any) action snuff has on the heart? I have a patient, aged 68 years, who is suffering from flatulent dyspepsia and threatened heart failure. He uses about one ounce of snuff weekly. Is this habit injurious and should the snuff be forbidden? Thanking you in anticipation,

I am, Sirs, yours faithfully,
Hull, Jan. 9th, 1905. JAS. SAVEGE, M.D. Aberd.

A REPUDIATION.

To the Editors of THE LANCET.

SIRS,—A portion of the daily press having copied the reports of some of my cases which were published in last month's issue of the *British Journal of Dermatology*, I should esteem it a favour if you would allow me to state it was done without my knowledge or consent.

I am, Sirs, yours faithfully,
Harley-street, W., Jan. 3rd, 1905. T. J. P. HARTIGAN.

ANTI-NICOTINE TOBACCO.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me of an anti-nicotine tobacco and what firm manufactures it?

I am, Sirs, yours faithfully,
Jan. 9th, 1905. H. D.

⁂ We have no knowledge of an "anti-nicotine tobacco" for pipes or cigarettes but it is just possible that such an article is made. There are cigars on the market from which a large fraction of the nicotine has been extracted but we have no experience of their qualities.—ED. L.

TUBERCULO-ALBIN.

To the Editors of THE LANCET.

SIRS,—It may be of interest to you to know that at the request of a number of patients who wanted to test its value upon themselves I gave tuberculo-albin a fair trial in six cases over two years ago. In no case did it appear to produce any benefit and in some instances it appeared to aggravate the symptoms. I have unfortunately still a quantity of the material beside me which I bought at that time, as far as I can remember, at a cost of 10*s*. an ounce and except for the glass stoppers and the bottles themselves consider the possession valueless.

I am, Sirs, yours faithfully,
Jan. 2nd, 1905. D. L.

◆

R. R. R.—The law is thus stated in Whitehead's "Church Law," second edition, at p. 179: "The duties of ministers and registrars are practically confined to enforcing the observance of the proper legal forms and ceremonies, but at the same time they are liable to punishment for performing the ceremony, knowing that the parties or one of them is either unable or unwilling to enter into the contract." An insane person cannot enter into the contract of marriage but it is not easy to imagine a case in which it could be proved that one of the parties was incapacitated at the time to the extent recognised by the law and that the clergyman or the registrar knew it. The exaction of any penalty, therefore, from the clergyman or the registrar must be extremely rare and we are not aware of any instance having occurred to which we can refer our correspondent. The difficulty of establishing the absence of intelligent consent to the contract of marriage was shown in the case of Scott *v.* Sebright and in that in which the Earl of Durham endeavoured to have his marriage pronounced void. Both these trials took place more or less recently and were reported at length in the newspapers.

Dict.—We do not possess the information which, we think, could only be obtained from the well-known manufacturers of various specialities.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

Pestis.—Mr. F. H. Joseph: Fugent—a New Stain.—Mr. G. MacDonald: On the Development and Course of the Opsonins in Cases of Acute Lobar Pneumonia.—Dr. W. Bulloch: The Variations in the Opsonic Index in Cases of Tuberculosis.

MEDICO LEGAL SOCIETY (Rooms of the Royal Asiatic Society, 22, Albemarle-street, W.).—8 P.M. Dr. J. G. Garson: A Case of Disputed Fracture of the Clavicle. Demonstration:—Dr. J. G. Garson: The Development of Invisible Finger-prints. Discussion on the Law relating to the Criminal Responsibility of the Insane (opened by Mr. A. D. Cowburn).

ROYAL STATISTICAL SOCIETY (9, [illegible] Strand, W.C.)—5 P.M. Paper:—Dr. R. Dudfield [illegible] of the Methods of Recording and Publi[illegible]ng on Public Health, with Suggestions for the Improvement of such Methods.

WEDNESDAY (18th).—SOCIETY OF ARTS (John-street, Adelphi, W.C.)—8 P.M. Paper:—Capt. L. James: Wireless Telegraphy and War Correspondence.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.).—5.30 P.M. Paper:—Dr. C. W. Buckley (Buxton): Climatology from a Medical Standpoint.

ROYAL [illegible] of Civil Engineers, Great [illegible] 7.30 P.M. Ordinary Meeti[illegible] Election of Officers and Council for the ensuing year. Address :—The President (Capt. D. Wilson Barker): The Connexion of Meteorology with other Sciences.

FRIDAY (20th).—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos-street, W.).—5.30 P.M. Cases and Specimens will be shown by Dr. W. H. Kelson, Dr. A. Morison, Dr. L. Guthrie, Mr. G. Pernet, Mr. F. Jaffrey, Mr. D. Armour, Dr. E. Pritchard, Dr. J. G. Emanuel, and Dr. G. Carpenter. Paper :—Mr. D. Drew: On a Case of Vesical, Ureteral, and Renal Calculus in a Child.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (16th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. T. C. Fox: Clinique. [illegible] Surgery of Simple [illegible] al, Hammersmith- [illegible] Various Diseases. [illegible] (Tottenham Hos- [illegible]

[illegible] nic [illegible] que. [illegible] ent [illegible] ry, [illegible] ties [illegible] by [illegible]) —

WEDNESDAY (18th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 [illegible] Clinique. [illegible] especially [illegible]

POST-GRADU[illegible] road, W.).—5 P.M. Dr. Beddard: Practical Medicine.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Demonstration :—Mr. Nourse: Nasal and Aural Accessory Sinuses.

[illegible]

FRIDAY (20th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. StClair Thomson: Clinique. (Throat.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. S. Taylor: Treatment of Various Diseases

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle street, W.)—9 P.M. Prof. Sir James Dewar: New Low Temperature Phenomena.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1904, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s.* carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Bath Weekly Argus, Glasgow Evening Times, Leeds Mercury, Cork Constitution Surrey Advertiser, Westminster Gazette, Sussex* [illegible] *Post, Notts Guardian, Dublin* [illegible] *Mercury, Sanitary Record,* [illegible] *Journal, The Scotsman, Highland News, St. Petersburg Medicinische Wochenschrift, Evening News, Morning Leader, Manchester Courier, &c.*

Communications, Letters, &c., have been received from—

A.—Mr. Alfred Ankerson, Sidcup; A Hospital Secretary; A. E. T.; Messrs. Allen and Hanburys, Lond.; Mr. F. W. Axham, Lond.; Mr. R. J. Albery, Lond. A. M. O.; Aberystwyth, Borough of, Accountant of.

B.—Dr. Leslie Buchanan, Glasgow; Mr. T. G. Barton, Chadwell Heath; Belfast District Lunatic Asylum, Resident Medical Superintendent of; *Birmingham Daily Post;* Mr. O. Berthier, Paris; Mr. C. Birchall, Liverpool; Mr. A. Berrill, South Woodford; Mr. F. A. Brockhaus, Lond.; Bolton Infirmary, Secretary of; Messrs. Brady and Martin, New- [illegible] Lond.; Dr. F. E. Batten, Lond.; Dr. W. C. Bosanquet, Lond.; Messrs. [illegible] and Co. [illegible] District [illegible] tion, H[illegible] Clinical [illegible] W. M. Birds, Liverpool.

C.—Mr. G. G. Collins, Rangoon; Mr. W. G. Copestake, Derby; Clayton Hospital, Wakefield, Secretary of; Messrs. Callard and Co., Lond.; Central London Throat and Ear Hospital, Lond., Secretary of; Claughtons, Ltd., Leeds; Mr. A. Campbell, Derby; Messrs. A. Constable and Co., Lond.; Criminal Investigation Department, New Scotland Yard; Messrs. Cock, Russell and Co., Lond.; Mrs. M. Coffin-Duncan, Douglas, Isle of Man; Dr. D. Cotes-Preedy, Lond.; Mr. F. W. Clarke, Chorlton-cum-Hardy; Condensed Peptonised Milk Co., Lond.; Mr. Sydney W. Curl, Norwich.

D.—Devonshire Hospital, Buxton, Secretary of; Durham, County Medical Officer of Health of; Messrs. Dawson and Sons, Lond.; Dudley Dispensary, Secretary of; Messrs. G. L. Daube and Co., Frankfort; Diet; D. L.; *Daily Chronicle*, Lond., Exchange Editor of; Messrs. Down Bros., Lond.

E.—Mr. W. McAdam Eccles, Lond.; Mr. C. O'H. Ewing, Ballymore-Eustace; E. C.

F.—Dr. P. C. Franze, Bad Nauheim; Faber suæ fortunæ; Farringdon General Dispensary, Secretary of; Messrs. S. Fawkes and Sons, Stroud.

G.—Dr. William Gordon, Exeter; Dr. Alfred Greenwood, Blackburn; Mr. Henry Gray, Lond.; Mr. George Graham, Lond.; Dr. Edwin Goodall, Carmarthen; Mr. E. H. Gordon, St. Louis, U.S.A.; Dr. F. R. Greenwood, Portsmouth; Glasgow Pathological and Clinical Society, Hon. Editorial Secretary of.

H.—Mr. W. Horrocks, Bradford; Major W. M. Hodder, R.E., Chatham; H. C. L; Messrs. Haar and Steinert, Paris; Dr James H Hunter, South Shields; Messrs. Hirschfeld Bros., Lond.; H., Lond.; Mr. H. Holden, Lond.; Professor R. T. Hewlett, Lond.

J.—Messrs. W. and A. K. Johnston, Edinburgh; Mr. S. James, Liverpool; Messrs. D. Hill Jack and Son, Glasgow; Messrs. Jones Bros, Bristol; Miss Edith Jameson, Eltham; Messrs. Jacob and Johnson, Winchester; Dr. J. G. Jones, Indianapolis; Messrs. Jewsbury and Brown, Manchester.

K.—Dr. Arthur Keith, Lond.; Dr. H. Cameron Kidd, Bromsgrove; Messrs. R. A. Knight and Co., Lond.; Mr. T. D. Kelly, Southend.

L.—Mr. V. Warren Low, Lond.; London School of Tropical Medicine, Lond:, Secretary of; Messrs. Lee and Nightingale, Liverpool; Mr. H. K. Lewis, Lond.; Dr. Lebon, Saargemund, Germany; L. G. H.; Right Hon. the Lord Mayor of London; London Open Air Sanatorium, Secretary of; Dr. E. B. Leech, Tarporley; Leicester Infirmary, House Governor of; Dr. A. Latham, Lond.

M.—Dr. R. J. Mills, Norwich; Mr. J. H. Morgan, Lond.; Metropolitan Ear, Nose, &c., Hospital, Secretary of; Monmouthshire Asylum, Abergavenny, Clerk of; Messrs. Marler and Marler, Lond.; Messrs. T. M. Mackenzie and Co., Invergordon; Dr. A. McDougall, Alderley Edge; Messrs. G. Mason and Co., Lond.; Messrs. C. Mitchell and Co., Lond.; Manchester Medical Agency, Secretary of; Medical Society of London, Hon. Secretary of; Mr. Leslie Miller, Lond.; Mr. R. Macdonald, Brisbane; Mr. Valentine Matthews, Lond.; Dr. Charles Mackey, *Patricroft;* *Mr. A. P. Murtz, Lond.;* Mount Vernon Hospital for Consumption, Lond, Secretary of; Dr. William Murrell, Lond.; Mrs. Morgan, Shoreham; Manchester Hospital for Consumption, Secretary of.

N.—Mr. C. R. Niven, Liverpool; Mr. Edward Nettleship, Nutcombe Hill; Dr. J. Neil, Oxford; National Hospital for the Paralysed and Epileptic, Lond., Dean of; Naval Surgeon; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.

O.—Mr. John H. Ogilvie, Birtley; Dr. Thomas Oliver, Newcastle-on-Tyne; Dr. Henry O'Neill, Belfast.

P.—Mr. E. L. Payne, Kew; Messrs. Peacock and Hadley, Lond.; Mr. F. Pridham, West End, Hants; Dr. John Phillips, Lond.; Mr. Victor G. Plarr, Lond.; Mr. Y. J. Pentland, Edinburgh; Messrs. Preston Bros, and Co., Huddersfield; Plumbers, Worshipful Company of, Lond.

R.—Dr. Arthur H. Rideal, Lond.; Dr. H. Rayner, Lond.; Royal Botanic Society of London, Secretary of; Royal Microscopical Society, Lond. Secretaries of; Dr. Henry Renney, Sunderland; Mr. T. E. Rickerby, Cheltenham; Dr. R. R. Rentoul, Liverpool; Rochdale and District Medical Society, Hon. Secretary *of;* Mr. J. Royle, Birmingham; R. T. P.; Messrs. Rebman, Ltd., Lond.; Mr. R. Redpath, Newcastle-on-Tyne.

S.—Sir W. J. Sinclair, Manchester; Dr. J. E. Spicer, Lond.; Messrs. Stevens and Co., Cape Town; Dr. N. M. Shaffer, New York; Dr. C. Slater, Lond.; Professor Wm. Stirling, Manchester; Mrs. Shackleton, Moone; Society of Apothecaries of London, Secretary of; Mr. Alfred Smith, Birmingham; Mr. J. Sheehan, Lond.; Mr. H. S. Souttar, I.M S. (retired), Rungpur; Messrs. W. H. Smith and Son, Liverpool; Dr J. W. Springthorpe, Melbourne; St. Andrews University, Dean of the Medical Faculty of; Dr. W. Mitchell Stevens, Cardiff.

T.—Sir J. Batty Tuke, M.P., Edinburgh; Miss A. B. Thin, Noctorum; Dr. J. C. Thresh, *Chelmsford;* Mr. A. F. Tredgold. Lond.; Tottenham Hospital, *Secretary of.*

U.—University of Manchester, Council of the; University College, Lond., Principal of; Universal Cookery and Food Association, Lond.; Universities of Glasgow and Aberdeen Conservative and Liberal Unionist Association, Lond., Hon. Secretary of.

W.—Mr. C. Williams, Lond.; Winsley [illegible] Secretary [illegible] Stanley V[illegible] Dr. A. E [illegible] Dr. Wyatt Wingrave, Lond.; Mr. F. J. Wylie, Oxford; Dr. S. West, Lond.; Mr. J. Walters, Bedlinog; Mr. F. Barclay Wilkinson, Lond.; Mr. W. Roger Williams, Clifton; Dr. W. B. Warrington, Liverpool; Mr. R. G. Wilson, Ilford; Messrs. H. Wilson and Son, Lond.; Messrs. Westmacott and Co., Lond.; Lieutenant-Colonel C. R. Woods, R.A.M.C., Birr.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. A. [illegible] Sheffield; Miss E. C [illegible] Mr. C. E. [illegible] Mr. J. J. Anning, Leeds; Miss L. Garrett Anderson, Lond.; Aberystwyth Infirmary, Secretary of; A. J. D.; A. W. H.; A. L.; A. H.; Apollinaris Co., Lond.; Messrs. T. and A. Armstrong, Lond.

B.—Dr. R. W. Brimacombe, Lond.; Benger's F[illegible] Dr. J. Ba[illegible] Boswell a[illegible] hampton; Sir William Broadbent, Bart., Lond.; Messrs. Burgoyne, Burbidges and Co., Lond.; Dr. T. C. Booth, Manchester; Dr. H. H. Borland, Glasgow; Miss Bullen, Lond.; Birkenhead Borough Hospital, Treasurer of; Messrs. H. Brown and Son, Huddersfield; Mr. N. Basak, Raipur; Dr. T. Berry, Rock Ferry; Dr. Fletcher Beach, Kingston Hill; Mr. J. P. Brooks, Wolverhampton; Dr. M. M. Bowlan, Lond.

C.—Mr. J. B. Cameron, Lond.; Dr. G. A. Crowley, Kinsale; Mr. E. Collins, Sawbridgeworth; Dr. A. W. Campbell, Nadroga, Fiji; Mr. J. J. Crowley, Cork; Messrs. Crossley and Co., Lond.; Messrs. Claye and Son, Stockport; Dr. G. E. J. Crallan, Bournemouth; Miss A. E. Charlesworth, Boscombe; Miss N. Court, Duffield; C. E. S.; Central News, Ltd., Lond.; Dr. E. Coleman, Lincoln; Messrs. T. Christy and Co., Lond.; Dr. R. Coates, Llanhilleth; *Croydon Corporation, Accountant of.*

An Address

ENTITLED

SOME THOUGHTS ON CONVULSIONS DURING INFANCY AND CHILDHOOD.

Delivered before the Fylde Medical Society on Nov. 29th, 1904,

BY HENRY ASHBY, M.D. LOND., F.R.C.P. LOND.,
LECTURER ON DISEASES OF CHILDREN, VICTORIA UNIVERSITY.

GENTLEMEN,—I am sorry to confess that I have nothing new or novel to offer you in my address to-night. But I will not pretend to apologise for discussing a subject familiar to every practitioner; the common things of this life are the most important and the common phases of disease are no exception. Movement enters largely into the life of everything that breathes; we are constantly doing something; our muscles are ever on the alert—are relaxing or contracting for the performance of some definite end. Coördinated movements are rendered possible by highly organised nerve centres which, on the one hand, receive impressions from the different sense organs of the body and, on the other hand, send out stimuli by a system of relays to the muscles. The nerve cells store energy ready to be released on call which, passing along the motor paths, evoke the muscular contractions. For the orderly progression of events the nerve cells must be in a normal or stable condition; the movements, whether reflex, instinctive, or voluntary, are all carried out in an orderly and coördinated manner.

In certain morbid states of the nerve cells there is an excessive sensitiveness to impressions or a deficient inhibition and the nerve centres appear to be at the mercy of every chance stimulus which comes along the afferent channels. Then order departs and chaos reigns; uncontrolled nerve discharges take place, giving rise to erratic movements, accompanied by a complete or partial loss of consciousness. In other words, there is a nerve storm which may be local or general and affect both motor and sensory centres. All through infancy the nerve centres are more susceptible to reflex stimulation, or perhaps we should say less under control than in later life, when the higher or inhibitory centres have become developed. The infant readily breaks out into tears, it is easily startled and angered, vomits from slight causes, and its temperature runs up with little reason. This instability or defective power of resistance to stimulation differs greatly in different individuals and certainly runs in families in the same way as epilepsy and insanity. Some infants, in spite of well-marked exciting causes, never suffer from convulsions, while others suffer whenever the digestion goes wrong. Neurotic women are very apt to have infants who suffer from convulsions. Comby relates how a woman who suffered from hystero-epilepsy lost five children from convulsions and a sixth also suffered. This hereditary disposition to convulsions is probably the most important factor with which we have to deal. But a disposition to convulsions may be not only hereditary but acquired, though in any given case both factors may be present. Rickets undoubtedly predisposes to convulsions; perhaps we ought to say that chronic indigestion, with the absorption of toxins into the blood, gives rise both to the bone changes seen in rickets and also renders the nerve centres unstable and ready to discharge from slight stimuli. It is certain that not every rickety child suffers from convulsions but a large proportion of children who suffer from convulsions between the ages of five months and two years are rickety. Given a maximum of hereditary or acquired disposition a minimum of stimulus will give rise to convulsions; or, on the other hand, a minimum of disposition requires a maximum of stimulation to produce the same effect.

Having laid some stress on the predisposing causes of convulsions let us consider the exciting causes or those which immediately precede the attacks. We may divide these for the sake of convenience into three or four groups. *Reflex*, in which the stimulus proceeds from the gastro-intestinal tract as in griping and colic, from the respiratory tract as in whooping-cough or bronchitis, from the internal ear, from the nose or mouth as in painful dentition. *Toxic*, as in the early stage of measles or influenza. *Central*, as in meningitis or syphilis of the brain. *Epileptiform*, when no cause can be found and often associated with signs of belated intelligence. We must, however, remember that often there is no well-marked difference between predisposing and exciting causes or between those which we might classify as central and reflex. It will be convenient to discuss some groups which in practice are fairly common.

Let us then first refer to the convulsions which are not uncommon in the newly born. With regard to their origin let me quote Sir William Gowers.[1] "During the first few days of life convulsions are not uncommon, but they probably always depend on direct injury to the brain during the progress of birth." And again, Spratling writes:[2] "It is a well-known fact that during the first two months of life reflex action is insufficiently developed and convulsions which appear at that time are almost always primarily cerebral and due to hæmorrhage." I cannot agree with these statements. I do not doubt that convulsions due to brain injury may take place in the newly born but I cannot think they are common; I believe they are much more commonly the result of gastro-intestinal disturbances due to artificial feeding and in some instances to epilepsy, the result of intra-uterine brain degeneration or disease.

The convulsions of the newly born are most common in infants who are artificially fed from the first and who are given diluted cow's milk which sets up flatulence and green curdy stools. There are clonic convulsions of the limbs, twitching of the eyelids, eyes, and face, dilated pupils, duskiness, drowsiness, and some fever. The fact that the convulsions are more or less one-sided does not by any means signify that they are not reflex. Any paresis would, of course, suggest organic disease but a slight hemiplegia may follow severe convulsive attacks and disappear in a few days or weeks. The fits may recur from hour to hour and the exhaustion may be extreme. In many cases, as I have already said, the abdomen is distended with gas, there is more or less griping, the stools are unhealthy, and the nates become more or less excoriated. Probably the starting point in these cases is an inflamed and overactive colon; possibly the absorption of toxins may have some influence on the nerve centres. We must bear in mind also that apart from the difficulty that some newly born infants have in digesting cow's milk there is during artificial feeding a greater risk of infection by the mouth than when the infant is fed from the breast. The same hands that attend to the mother's diapers and the infant's napkins prepare the food and feed the infant; the nurse often puts the teat of the feeding-bottle in her mouth before feeding. The newly born infant is very intolerant of infection by the mouth and colitis, fever, erythema, and convulsions result. How careless nurses are in many respects must be apparent to all. I often notice when an infant is brought to me that the *feeding-bottle containing the baby's food is carefully* wrapped up in a spare diaper, the latter being handy in case of necessity and at the same time fulfils the useful purpose of keeping the bottle warm. Surely no well-trained nurse would be guilty of such an abomination.

My own belief certainly is that convulsions occurring in the newly born, especially if the infant is being artificially fed, are usually reflex or, at any rate, not due to any brain injury. The short-cut cure in such cases is a wet nurse; failing this raw asses milk or whey made from clean, fresh cow's milk diluted with a solution of milk sugar; and if possible the services of a capable trained nurse should be acquired. In some instances convulsions in the newly born are due to ante-natal causes. Let me illustrate this by a case from my notes and one which is not altogether uncommon. "The patient had an easy birth; he belonged to a neurotic family of seven and came 14 years after the last child; convulsions of a mild type began three days after birth; he was breast fed for eight months; he had no indigestion but the fits recurred from time to time. He walked at two years old. When seven years of age he still suffered from slight fits; head measured 18¼ inches only; he has a high arched palate; he is babyish and mischievous and can only say a word or two but can understand a good deal, but he is clearly imbecile." It is pretty certain that this is not a case of birth injury but of defective development of brain during intra-uterine life, resulting in imbecility and epilepsy. It is possible that such cases are syphilitic but of this there was no evidence in the above case.

---

[1] Diseases of the Nervous System, p. 713.

[2] Epilepsy and its Treatment, p. 75.

Let us turn now to the period of dentition which is in the estimation of the public the period *par excellence* for fits. In the language of the out-patient room: "He is plagued with his teeth"; "I have lost four children with teething fits"; "*He has fits such as all children have with teething.*" But the alienist is hardly less emphatic in his estimation of the importance of the period of dentition in causing convulsions. In a recent work I read the following: "It has long been the writer's belief that *dentition when severe and acting on an organism that bears the impress of transmitted weakness of a necessary kind* plays an important part in the production of epilepsy in early life." Another celebrated alienist writes: "I have seen the convulsions of dentition followed by a prolonged delirium ending in idiocy, or in true epilepsy or insanity of adolescence." Surely, as far as dentition is concerned, there is a great deal of exaggeration here and a suggestion of the arrangement by which the tail wags the dog. The period of dentition covers most of the first two years of life; during this time some tooth or other is being cut, or the gums are swelling in anticipation of their eruption. You cannot see lumps of curd or grape skins in the stomach and you forget to put your hand on the abdomen and feel for a griping colon, but you can see the swollen gums or the edge of an incisor tooth and if an explanation of the fit is necessary dentition is there as a very present help in time of trouble. Everyone knows the discomfort and irritability caused by sore gums and stomatitis but when I am told that dentition plays an important rôle in producing epilepsy and insanity I dissent. By far the commonest exciting cause of reflex convulsions is gastro-intestinal disturbance, accompanied by colic and griping, due in many cases at least to overfeeding with cow's milk. The decomposition of the curd plays an important part; the stools are pasty, lumpy, and foul-smelling. In other cases bronchial or naso-pharyngeal catarrh or middle-ear suppuration may be the exciting cause.

One type of reflex convulsions occurring during early life which claims our attention on account of its frequency and importance is spasm affecting the muscles of the glottis and respiration. Child-crowing, as it is called, or laryngismus, is practically always associated with rickets and especially affects infants from the age of four or five months till the end of the second year. Adduction of the cords is easily produced during childhood. The infant cries from slight causes and the cords are approximated for the purpose. Watch an infant under chloroform for an operation; if the operation is commenced before the infant is deeply under the anæsthetic directly the knife cuts the skin there is a noisy inspiration from spasm of the adductors. The same thing happens when vomiting or retching is imminent. Normally the adductors are inhibited during inspiration but the wounded cutaneous nerves cause reflex spasm of the adductors which is, perhaps, a sort of contribution towards a cry. A similar adductor spasm is produced in animals by galvanising the central end of the superior laryngeal nerve and also the splanchnics; Horsley and Semon have shown that stimulation of the base of the left third frontal convolution in the monkey produces adductor spasm and expiratory efforts.

Assuming there is in rickets what Dr. J. F. Goodhart would call an "imbecile respiratory centre," or, in other words, a condition of unstable equilibrium, there is a reflex spasm of the adductors of the cords from slight causes. Among these causes we may mention emotion, such as anger, irritation of the fauces, as in catarrh, and discomfort or pain in the gastro-intestinal tract. We say of an individual in a highly emotional state that he was speechless from anger; the violent effort made to speak prevents the deep inspiration from being taken which is a necessary preliminary for a violent declamation. Watch an attack of laryngismus in an infant. He has an irritable temper, easily provoked; something goes amiss; he gives a series of cries to express dissent; then comes the attempt to make a very deep inspiration in order to give still more emphatic vent to his feelings but he is in too great a hurry to make himself heard and respiration is arrested in what physiologists call "expiratory standstill." Vigorous but futile efforts are made to inspire, while the face works; presently a condition of semi-asphyxia intervenes which inhibits the emotional disturbance and expiratory spasm and air is drawn into the lungs with a crowing sound. Other attacks follow till the child falls asleep. In the slighter attacks there is partial spasm only and the child crows from time to time, or the crowing is continuous both during the day and during sleep. In some cases of laryngismus there is an association of tetany, the overflow of energy passing into the muscles of the limbs and giving rise to continuous spasm. Let us remember there are other forms of laryngeal spasm besides laryngismus in association with rickets. The congenital stridor of young infants is, I believe, a reflex spasm. In croup and whooping-cough a similar spasm occurs.

Convulsions in some instances are of cerebral origin, being due to some form of brain irritation. Among these causes may be meningitis, encephalitis, thrombosis, hæmorrhage, tumours, and syphilis. In meningitis the fits may occur at quite the initial stage or towards the end of the case and herald the fatal termination. In the former case the diagnosis may be difficult. The question will present itself, Are the convulsions reflex from the alimentary canal or are they due to some commencing organic disease of the brain such as meningitis? I doubt if the nature of the fits themselves will lend much assistance in the diagnosis, as both reflex and fits secondary to some brain irritation may be more or less one-sided and accompanied by a temporary retraction of the head and coma. In fact, we may have the same type of fit whether there is an early meningitis or tumour, or a toxic condition of blood with or without reflex irritation.

There is, however, one type of convulsion occurring during infancy which is distinctly of the Jacksonian type and that is a syphilitic softening of the cortex of the brain. An infant a few months old who has suffered from coryza, erythema, and epiphysitis begins to suffer from slight one-sided convulsions; there is a slight series of twitchings of an arm or leg which frequently recur. There is a momentary loss of consciousness or only a dazed look. Later the twitchings may affect the opposite side and then gradually a contracture of the flexures of the arm and leg first affected takes place and the infant shows signs of less and less intelligence. The post-mortem examination shows a patchy softening of the grey matter of the cortex with degeneration of the arteries. Sclerosis seems to follow the softening. Frequently recurring slight fits without apparent cause during infancy suggest epilepsy associated with more or less imbecility or mental feebleness. The convulsions may be so slight as to be overlooked or may pass as "faints." But as time goes on it becomes only too clear that the mental powers are not developing at the normal rate. The infant takes no notice of his friends, or he is constantly screaming and giving the unfortunate mother no rest day or night; later he is mischievous and passionate. Slight general convulsions which frequently recur without apparent cause and with signs of delayed intelligence are of the worst possible augury with regard to the child's future. This combination of imbecility with fits would seem to point to some failure of development taking place during ante-natal life which interferes with the higher centres and renders the nerve cells unstable.

Where does the dividing line come in between infantile or reflex convulsions and epilepsy? Between a temporary condition of unstable nerve cells and a more permanent condition of instability? In the majority of cases of infantile convulsions, especially those which are associated with rickets, the tendency to convulsions becomes less and less as the child becomes older and finally they cease to recur. On the other hand, we find perhaps 10 per cent. or more of those who suffer from epilepsy in later life have suffered from infantile convulsions. Then there are a certain number of cases, especially in children from three years to seven years old, in which the diagnosis is uncertain as to whether they are reflex or are true epilepsy. If we can clearly recognise some definite reflex cause such as worms, dyspepsia, or a febrile attack as the exciting cause, we may have good reason to look forward hopefully to the future. The convulsions may be reflex occurring in a neurotic child and they may probably cease to occur as the nervous system becomes more robust and less easily influenced by eccentric stimulation. If the attacks recur without obvious cause and especially if there is any mental peculiarity about the child the prognosis is much more grave. In any case when fits occur in early or late childhood they must be taken as evidence of a neurotic constitution which will require judicious handling all through early life.

So far we have been discussing attacks of convulsions which, however much they may threaten life during the actual attack, pass off and leave no temporary or permanent disability. There are, however, certain attacks which are clearly very serious in their nature and when the storm has passed away it is found that a certain amount of wreckage remains. In many cases it is certain that severe damage has been done, but it may be impossible to say how or what. We ask ourselves, Have the convulsions been toxic?—as, for instance, when they occur in the early stage of measles,—Has a meningeal of multiple bleeding *taken place which has damaged some nerve paths or centres?* In other words, has the lesion been a consequence of the fit? On the other hand, has there been a thrombosis or focal encephalitis which has given rise to both the convulsions and the paralysis which is left? In some instances at least there is post-mortem evidence of multiple hæmorrhages which suggest venous engorgement secondary to the convulsion and it seems probable that in some cases this is the true explanation. But, on the other hand, we find an anterior poliomyelitis and also convulsions and a hemiplegia of cerebral origin occurring in the course of measles, and one is tempted with the suggestion that in one case there is a focal inflammation of the grey matter of the cord and in the *other case a focal inflammation of the grey matter of* the cortex.

In these serious attacks of convulsions there is usually more or less high fever, perhaps 104° or 105° F., one convulsive seizure is followed by another, perhaps for many hours, and is followed by deep coma which lasts from 24 hours to a week or even more. This state closely resembles the status epilepticus of adults and has been called the status eclampticus. Doubtless such attacks have done duty on various occasions for "brain fever." Some of these attacks come on during whooping-cough, measles, or other infective diseases. Hemiplegia is one of the most important complications of this state; the paralysis may not be noticed till after the convulsions have passed away. In some cases it is slight and temporary; in others it is severe and remains for life and the paralysed limbs become spastic. In the latter case there is often feeble-mindedness and sometimes post-hemiplegic epilepsy. Among the feeble-minded children brought up for examination at the special schools in Manchester 10 per cent. had hemiplegia dating from attacks of infantile convulsions. But apart from any paralysis a serious convulsion may leave behind it a condition of the *mental powers altered much for the worse.* Whether this is the result of the nerve storm or owes its origin to some cause such as encephalitis is uncertain. Let us take the following case as an illustration.

The patient was a boy, aged four years. The family history was good. He learned to walk at 17 months and talked at two years. He was a boy of normal intelligence till he had measles at three and a half years of age. He was suddenly seized with convulsions and high fever and was in *deep coma for two days, the rash of measles appearing* on the third [illegible] blind for a few [illegible] months after h [illegible] vulsions his temperament has changed; from being an easily managed boy he is now irritable and difficult to manage. He is very babyish for his age, is mischievous and destructive, and his attention is constantly wandering.

This is, perhaps, not an uncommon type of case; there are a *series of fits followed by coma*; when the patient recovers consciousness it becomes clear that some damage has been done to the highest level centres; but what the nature of the damage it is not easy to say. In not a rare class of case the child recovers completely from the status eclampticus except that for many weeks he is blind. In epilepsy visual auræ are not uncommon, the patient sees *flashes of light* or there is sudden darkness before the fit supervenes. In rare epileptic seizures the sudden and temporary *loss of sight is the only phenomenon* which takes place. Very possibly the accounts handed down to us from past ages of people being suddenly smitten with blindness were cases of epilepsy. Dr. W. W. Ireland speaks of a boy who used to say that at the onset of a fit his "e'en gang black." It seems likely that the visual area of the cortex is involved in the discharge and a state of exhaustion remains. Let me quote the following case.

The patient was *aged one year. The child had severe* whooping-cough for a *week or ten days*, when he was seized with general convulsions lasting for several hours; these were followed by deep coma for 12 hours. When I saw him with Mr. J. H. Hacking he was collapsed and insensible, with contracted *pupils and a temperature of from* 101° *to* 102° F. He gradually recovered consciousness but remained drowsy for some days, then it was noticed that he could hear what was going on, as, for instance, the preparation of his meals, but could not see. When I saw him again some two months after the fits he was bright and lively but was blind. The pupils acted to light and were normal; the optic discs were also normal. He could sit up, chirp and crow, and say "dada" and "mamma," he could not see his bottle, but when it was put into his hands he grasped it and *carried it to his mouth. He took no notice of a bright* electric light brought near to his face. From this time he gradually improved and between three and four months after the attack he could see as well as ever. I have never seen a case in which permanent loss of sight followed convulsions. In these cases the pupils are active and normal, which would suggest that the lesion or failure of function is higher up than the pupil reflex centre.

Rare cases have been described in which there was an attack of convulsions followed by coma and when consciousness was regained it was found that the patient was deaf. This was so in the following case.

The patient was a girl, aged eight years. Before the *attack she was a* bright, intelligent girl in the second standard at school. One hot day in July, 1904, after returning from school she was seized with convulsions and high fever. The convulsions lasted for seven hours; she was comatose for more than a week. After regaining consciousness she was drowsy for some days and found to be completely deaf. According to her mother's account there was no discharge from the ears or any pain at any time. She could not hear a word but answered written questions in a low voice. Examined by Mr. F. H. Westmacott three months after the attack he reported that she could hear the tuning-fork held in contact with the skull but not when held close to her ears. There was a perforation of one drum but no discharge; the membranes were thickened and drawn inwards and the ossicles were fixed. What lesion had taken place during the acute attack it is difficult to say—possibly an acute inflammation of the labyrinth and middle ear without pus. Five months after she was *still* completely deaf and waiting for admission to a school for the deaf and dumb.

In some cases a temporary aphasia is left after a severe series of convulsions, either with or without being associated with hemiplegia. In one case coming under my observation a boy, aged two and a half years, had a series of severe convulsions in the course of whooping-cough, which was followed by aphasia which lasted two months. There was no deafness but he answered by gesture and pushed his plate when he wanted more to eat. During this period he was heard to talk once or twice in his sleep. When once he began to say a word or two he quickly regained his old power of chattering and no difficulty of speech remained. I have related these cases as I was anxious to call attention *to the alarming* complications which at times accompany severe convulsions. The onset is sudden and the fits are severe and follow one another rapidly. Then comes the comatose stage which is often prolonged for a week or more. In some of these cases death takes place and nothing is found post mortem, at least to the naked eye, but a *very wet* brain and fluid in the *lateral ventricles Presumably the* effused fluid is secondary to the congestion of the vessels, the result of the severe convulsions. In other cases recovery takes place slowly without a [illegible] I have already pointed out th [illegible] which complications remain [illegible] fit has passed away is uncertain. Post-mortem examinations are badly wanted and a very complete histological examination of the brain is required.

To attempt to discuss the treatment of convulsions would mean *discussing the* treatment of the many diseases or conditions with which convulsions are associated. This I will *not attempt* but will be content with making a few remarks. As far as the acute stages of tonic and clonic spasms are concerned we shall find subcutaneous injections of morphine the most powerful remedy for quickly allaying the irritability of [illegible] ments. [illegible] mus is [illegible] six months old, may be given one-fortieth of a grain and an infant one year old a twentieth subcutaneously. Avoid the use of morphine in wasted and feeble infants and also in newly born or very young subjects. Inhalation of chloroform is another quickly acting remedy but its action soon ceases when withdrawn. Chloral given by the rectum is slower in action but its effect is more durable. Four or five grains of chloral dissolved in water or in egg-and-milk mixture may be given to an infant aged from six months to a year. The bromides are too slow in action to be of any use during the fits but later mixed bromides may be given to prevent their recurrence. It is wise in all cases to give calomel by the mouth if the patient can swallow to clear away any foul curd or irritating matter in the intestines.

What can be done to prevent the continued and dangerous irritability of the nerve centres? I have at times seen infants with simple laryngismus inclosed in steam tents, in hot stuffy rooms, where no outside air has been admitted for weeks. We shall all agree that instead of being kept in a used-up hot-house atmosphere they ought to have been enjoying the breezes on the sea shore. What we want is a hardening and bracing up of the nervous centres and an improved condition of health. For this purpose a hot-house atmosphere is the worst possible. No doubt too great changes of temperature are not to be recommended all at once, especially in those cases where laryngismus is associated with laryngeal or bronchial catarrh. Give the child a warm bath every morning and then sponge or douche him with cold salt water, taking care to rub dry and get a reaction. Give him more and more fresh air every day and get him off to the seaside as soon as possible. The success which has attended the open-air treatment of the pneumonias, of whooping-cough and measles should open our eyes to what can be done in this direction in other diseases, such as the functional diseases of the nervous system, during early life. In all forms of convulsions, especially those associated with rickets, open-air treatment is likely to be successful. There can be no difficulty in summer in keeping the infant out all day and supplying him with fresh air freely at night. In colder weather great attention should be paid to the clothing, keeping the feet warm, and sheltering from high and blustering winds. If these matters are attended to let the patient be outside in the coldest weather. The diet must be carefully regulated; infants suffering from convulsions are often given too much milk, their stools are foul and pale; intestinal intoxication plays an important rôle alike in rickets, convulsions, and epilepsy.

What are we to advise with regard to the fits of older children, whether admittedly epileptic or belonging to a borderland class, which we call "reflex fits," but with a certain mental reservation? Diet is of great importance and a careful consideration of the idiosyncrasies of the individual. Speaking generally, a mixed diet, moderate in amount, avoiding overfilling the stomach and overworking the digestive organs, will answer best in the long run. To forbid meat and to allow the child to take large quantities of starches and sugar is bad policy. Heavy meals of oatmeal porridge, rice pudding, and bread-and-butter are likely to lead to intestinal fermentation and distension of the abdominal organs with gases. It is well in the first place to cut down the starches by forbidding porridges and puddings and only small quantities of bread-and-butter. Cocoa, with egg and toast for breakfast; a reasonable quantity of beef or mutton or poultry for dinner with cooked vegetables and stewed fruits; and cocoa, toast, and treacle or honey for tea. Some children are given too much milk; mothers will boast that by hook or by crook they get into their children a quart of milk a day in addition to their meals and expect to be commended for their motherly instincts. Then they say that the child has lost his appetite and meat essences and raw beef juice are given at odd times; if these fail to cure the child they suggest a tonic and port wine at 11 in the morning. All these maternal insanities have to be combated, a carefully selected and frugal diet has to be prescribed, some cascara in divided doses or a saline mineral water, to secure regular and fairly free evacuation of the bowels.

Then there remains the important question of school which is so often put to us by parents. Probably the answer is expected, "On no account let the child do any lessons but let him 'run wild' for six months." If "running wild" means involuntary idleness, an aimless and empty existence without discipline and control, and a more than ever concentration on self, then "running wild" is the worst possible treatment for fits. By all means arrange for many hours in the open air but find objects of interest, outdoor work, and outdoor play. Then consecrate some part of the day, be it only a couple of hours, to some indoor employment. There is no real fear of overworking juvenile brains if the subject matter is not concerned with desks and books but is made interesting and the employment or lessons are short and varied and intervals of outdoor relaxation are frequent. The child is a social animal and the society of other children, if well under control, has a powerful influence for good and the more neurotic the child the more need is there for his contact with others. To allow the neurotic child to feel that he is the first to be considered, to let him think that every little ache, every little disappointment, and every discomfort are sore trials is to be doing all that can be done to blight his future. Give him daily employment, everything well within his powers, and look for accurate performance. Defer if you will all abstract learning till a later day, but find for him an active and occupied life; lend him a firm hand that may help to forge and strengthen the links of voluntary power and self-control which will prove important factors in preventive medicine and save many a sorrow.

THE PRINCIPLES OF TREATMENT OF PNEUMONIA.[1]

BY WILLIAM EWART, M.D. CANTAB. AND DURH., F.R.C.P. LOND.,

SENIOR PHYSICIAN AND JOINT LECTURER ON MEDICINE AT ST. GEORGE'S HOSPITAL; SENIOR PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN.

INTRODUCTION.

THIS advocacy of an active treatment for pneumonia may be an unnecessary pleading with some. If so they are the exception. The present fashion is rather the other way, and patients are lucky who may find in the body of the profession some of that hopefulness too foreign to its teachings. My theme is: "*Non nocere, sed agere.*" Our hope lies in the fact that pneumonia is not a fulminant disease killing the patient on the first or even the second day but later, if fatal. Our opportunity is to utilise that precious interval of safety and to strike early and strongly. The weapons are those of nature, provided by the heart and the lymphatic circulation, and such simple and safe remedies as may oppose the coagulation of fibrin and encourage its reabsorption. This is the general plan which I must endeavour briefly to describe.

THE PRESENT SITUATION.

Not very long ago an important debate was held in the United States on the relative value of medication by tonics or by vascular depressants. That any doubt should exist upon so fundamental a question describes the therapeutic position and our own. But the familiar request, "Give us the treatment of pneumonia" cannot be gratified in a few words. There is no single treatment for the disease, but only individual treatments for the sufferers—a reservation which must apply to any suggestions laid before you to-day.

Only two months ago my senior consulting colleague, Sir Henry Pitman, now in his ninety-seventh year, who retired from the active staff of St. George's Hospital before I was born, was telling me in his firm clear voice, "We used to bleed them in those days and they got well." Bleeding was, however, only part of the treatment. We seem to have lost the old art of treating pneumonia; we have not at present developed any new one and we are now largely living in the future hope of an antidote and of a preventive. It is true that here and there tradition has preserved in old medical families much of that which was good in the old-time treatment, and, again, a few men of exceptional clinical instinct and enterprise have struck out new lines for themselves with encouraging results, but the representative body of medicine has been under a spell and its oracles are dumb.

THERAPEUTIC INACTIVITY AND ITS CAUSES: IS IT JUSTIFIABLE?

On one point only I do not hesitate to be dogmatic. In presence of pneumonia we should be "up and doing." Hopefulness is essential to our usefulness and a passive attitude is hardly consistent with our recent advances in pathology and pharmacology. The therapeutic paralysis which had crept over medicine early in the last century was an after-wave of the destructive scepticism of the eighteenth century. As a fact, medicine and therapeutics were ill prepared then for the ordeal of critical analysis or to supply experimental evidence, and further, havoc was worked by the statistical method, which was applied prematurely to clinical questions from a growing desire for mathematical proofs. The calculating machine was right but what of the facts? C[illegible] as that pne[illegible] that all forms of treatment are useless or bad, and that the best course is "no treatment." To save appearances the mischievous euphemism "expectant treatment" was invented and it usurped the place of a precept. We have witnessed its paralysing influence in phthisis, in typhoid fever, and almost to the present day in pneumonia where the figures are alleged to show a fairly uniform death-rate under all varieties of therapeutic conditions. Were this allegation admissible there would be no object in my further addressing you. But it shall not pass unchallenged. In the first place the cases grouped together are of absolutely different kinds. Pneumonias supervening in exhausted vitality from extreme age, chronic diseases or intoxications, &c., are a *modus moriendi* and are inadmissible as tests for the value of remedies. Others are, owing to the relative mildness of the attack or to the superior stamina of the subjects, capable of spontaneous recovery without, or even in spite of, any interference. These, too, are not available as tests.

---

[1] An address delivered at Ramsgate on Dec. 1st, 1904, before the Isle of Thanet Division of the East Kent Branch of the British Medical Association.

Moreover, even in the remaining group which is the real field for therapeutic usefulness there are two unknown quantities varying with the individual—the relative virulence and amount of the infection and the innate power of resistance variously modified; and these were often the deciding factors when our treatment had been credited with success or failure. *Further doubts also arise from our clinical* limitations. We have known remedies to be triumphantly reinstated in modern therapeutics which had previously been rejected as inefficient because then employed in cases, in doses, or in circumstances which rendered them inoperative. The effect of these influences, and above all the conflicting and too often discouraging results of individual practice, has been to puzzle and to cramp our recognised teachings till therapeutic confidence and discrimination have almost disappeared in our generation, whilst the fatality of the disease continues its appeal.

Meanwhile the "specifics," of which there is a perennial supply from abroad, have not obtained a foothold in this country, for the good news that "pneumonia is under control" has not yet been flashed round the world. The same also applies to the only definite plan of treatment which now obtains a large following, that of raising the vital functions by peripheral stimulations. You have all heard, and some of you may have practical experience, of these bathings (only admissible in the case of children), spongings, cold packings, affusions, alternating cold and hot applications, and other devices for which doubtless there is much to be said. But this Spartan method claims so much time and energy as practically to exclude other treatment more suited to the urgencies of the hour. Very serious, too, is the responsibility of going counter to nature's prayer for rest. And how difficult to apportion the stress of this responsible treatment to the requirement and to the capabilities of each case! In short, I cannot regard this as our final therapeutic formula for pneumonia.

To recapitulate. Our present position is one of perplexing uncertainty: *ex cathedrâ* no strong line of treatment nor any guidance as to the value of the various opposing suggestions; on the other hand, definite forms of treatment are recommended by small minorities, viz.: (1) by individual believers in some specific remedy, and (2) by the supporters of plans of management, such as (*a*) the antiphlogistic or depressing plan, (*b*) the tonic plan, (*c*) the complete rest and feeding plan, and (*d*) the stimulating and rousing plan. The result as regards practice is that the bulk of the profession deem it wise to remain neutral and the patients bear the consequences. This is why, so late in the history of pneumonia I venture to invite you to join me in searching out the principles of its treatment. I propose to sketch the line which I am now following in connexion with a case as an illustration. Taken alone it can prove nothing, for all cases differ. But other cases, perhaps many of them, may closely resemble this one and might be equally benefited by the same measures.

THE MARCH OF THE DISEASE.

Pneumonia is known to be only one of the possible manifestations of a more or less general infection. Departures from the classical types had long ago been noticed in which was described a period of incubation lasting a week or more. The actual invasion may occur elsewhere before striking at the lung, or rarely the lung may escape almost entirely and the diplococcus may expend its virulence upon other parts, particularly the serous membranes and the joints. The mysteries enacted within the lung are in a great measure hidden from us. The rigor and attendant collapse may be regarded as a violent shock to the medulla through its afferent nerves, or perhaps as an invasion of its tissues. So great a commotion could not be the deed of one or of a thousand microbes; the rigor has therefore the significance of the time signal of the exploding effect upon the nervous system or of the entrance into the blood of a charge which had for some time been accumulating somewhere at the periphery, in the tonsils, the lungs, or elsewhere. Henceforth the lungs are at the mercy of the enemy, and yet not in their entirety, for there is significance in the following facts: (1) that in their greater part they remain free from invasion; (2) that the invasion is not only *not general* but *not even multiple* in either lung though it may occur in both; and (3) that a large area is affected at once and that the secondary infections which may occur are commonly continuous (as though by extension) with the main lesion. All this, as well as the rigor itself which is suggestive of some embolism, points to a definitely local invasion and to a lodgment of infective material, more probably in the air tract or blood-vessels than in the lymphatics.

We cannot stop to consider the serial evolution in the lung of the several morbid stages which are sometimes displayed post mortem when a progressive invasion ends in that wholesale phagocytic disaster and annihilation known as "grey hepatisation." Red hepatisations, airless congestions verging on consolidation, [illegible] sticky semi-œdematous c[illegible] [illegible]r lesion. I mention them in illus[illegible] are noted in our clinical signs. That the main consolidation is a regional reaction to the original lodgment is rendered probable by the post-mortem appearances described But this too liberal provision by nature to lock up the invaders is in itself a danger. As pointed out by my friend Dr. Andrew H. Smith of New York, the extensive effusion of fibrin is really a "breeding ground" for the diplococci, and this enormous supply of pabulum is the explanation for the overwhelming amount of poison manufactured by them in the lung and thrown into the circulation. According to this view the coagulation of the fibrin is *the danger*, and this should be borne in mind in our treatment.

THE CLINICAL STAGES.

The rigor constitutes a serviceable time-mark; but the following events are not to be registered so definitely and are perhaps not identically timed in all cases. Tubular breathing becomes audible earlier in some, later in others, but seldom before the lapse of 36 hours, and then rapidly increases in intensity and extent. During the interval there is a characteristic suppression of the vesicular and bronchiolar respiratory murmur over the affected area, which in the absence of any bronchitis carries with it the interpretation, also supported by the appearance of rusty expectoration, that the congestion is already so heavy as to impede the elastic function of the alveoli and partly to obstruct the entrance of air. Capillary oozing, which now sets in more freely, probably relieves the local turgor and the wall tension to the extent of restoring some vesicular respiration of a modified type. The advent of the fine inspiratory crepitation informs us that the part is not consolidated but that exudation of plasma has begun and that it has not yet filled the alveoli. Its continuance in some cases side by side with tubular breathing is usually regarded as evidence of a progressive extension of the pneumonia. But in some cases we might draw the happier inference that the plasma has remained in a semi-fluid state and does not yet completely plug the air cells.

Another important inference also arises. Fine crepitation tells that at that stage the corresponding bronchioles are not sealed, though they may become sealed subsequently. And I may in passing draw your attention to the fact that neither during its effusion nor during its reabsorption does any of the plasma dilute the tenacious hyaline mucus which appears to be derived exclusively from the congested bronchioles. It almost seems as though the spongy tissue were in a retentive attitude or its abnormal contents too sticky for ready expulsion. This stagnation *in profundis* in spite of open ways is still more striking in connexion with the looser and larger bubblings of crepitatio redux. The cases of persistent fine crepitation on the one hand, and on the other the much more unusual cases where even medium-sized bronchi are plugged by overbrimming exudation, serve to demonstrate that the degree of the exudative process and perhaps its quality may vary widely.

Let us bear in mind these successive changes corresponding to the five clinical stages of (1) invasion, (2) congestion, (3) exudation, (4) consolidation, and (5) resolution. I was almost passing over the highly suggestive phenomena of crisis, not so abrupt as the initial rigor, and yet sufficiently sudden and rapid as to remind us of a vascular if not of a vaso-motor event on a large scale. The warm sweat of recovery, conceivably excited by the products of the ripening intra-alveolar fibrin, just as the cold sweat of grey hepatisation is determined by the massive outpouring of the toxins, however it may otherwise work, certainly operates towards temporarily reducing the vascular fulness and stagnation. Within a few hours congealed life is started afresh into activity and the shrinking fibrin releases its pressure upon the collapsed or obstructed blood capillaries. Circulation is restored and the rest is a huge phagocytic banquet. There are other sides to the clinical picture—the cardiac, the hepatic, and the renal, but I must pass on to our chief subject.

THE VARIOUS ASPECTS OF TREATMENT.

(*a*) If we could, we should prefer to forestall the disease; this in the future will become the preventive treatment by immunisation. (*b*) If we knew, we should stop the invasion at its onset, by the wholesale poisoning of the micro-organisms. But meanwhile during the remaining interval of our ignorance the mortality is but slightly diminished by (*c*) the restorative and (*d*) the symptomatic treatment, the need for which will never cease. We want something more, (*e*) a curative, or at least palliative, treatment on the best rational lines. This we can study to-day in the brighter light of modern pathology.

The definite objects before us are: (1) To arrest the morbid process, by other abortive measures than the missing antitoxin; (2) to restrict the invading host, though we cannot stop it; (3) to destroy or to neutralise the poison by the vital energies; and (4) to hasten its elimination by every possible help. The individual means to these ends may be inadequate at first, or even mistaken, but the plan is good and the policy sound. Bear with me, then, if I should delay you with details almost trivial or with suggestions less practical than those which I hope you will yourselves offer.

THE PRINCIPLES OF ACTION.

1. *Prompt and assiduous treatment.*—Nowhere is this more vital. In all pneumonia the opportunity for curative treatment is brief and occurs early; all the rest is mere work of rescue and success is a question of vitality. So rapid is the march of events that our treatment has to be watched and varied almost constantly. We have counted the days in the pathological process; much more essential still that we should count the days of treatment. Nay, during the first day it is necessary to count the hours, whilst each hour has its changing indications. Lasting supplies of any one medicine are not needed. What is then wanted is the physician's almost constant attendance to observe, to judge, and to act.

2. *Decisive and, if possible, abortive measures.*—Happily during that period a safe opportunity exists for the application of adequately active measures which if delayed could neither be tolerated nor possess the same efficacy. In the worst infections and in all devitalised subjects this early chance is the last chance. All disease has a functional stage; the local mechanisms are then working badly, but still they are working, and conceivably they may be made to work better and, if so, yet better still in an upward progression. Not so once local paralysis has set in. This use of the term "functional" is, I admit, rather free, but it is practically descriptive of the conditions. In the early congestive stage the ways are still open and things are moving still, if only they could be made to move again quickly and in the right way. To induce them to move is the work of the earliest and probably least difficult stage of treatment. To soften thickening exudations and to promote their absorption when liquefied is the urgent indication at the next stage of the disease.

3. *Revulsion*, or the abrupt check of the congestion and incipient exudation, is a possibility not to be given up and supported by some strange facts. I may remind you that surgical treatment has been tried by isolated observers in the shape of acupuncture of the pneumonic lobe of the lung with averred favourable effects, probably worked through the nervous system. On the other hand, there may be such remedies as vascular revulsants which may abruptly check the congestion and the exudation. My former experience of the remarkably rapid effect of bulky intravenous injections of attenuated solutions of silver albuminate (protargol), which has been confirmed by the subsequent experience of others, among whom may be mentioned Professor Netter of Paris, is suggestive in this direction. But we are not dealing now with any such heroic methods but with simpler ones such as may be applicable in any cases if only taken in time. We should not forget that revulsants are not necessarily violent measures; in pneumonia none such is admissible. Cutaneous counter-irritation, blistering, and suitable internal remedies, although of the nature of lighter touches in treatment, may give vaso-motor visceral effects not less decided than those witnessed in some other acute affections. The entire treatment which I have to recommend for the first few hours might in a broad sense be included under revulsion, but it belongs largely also to the following headings.

4. *Defibrination.*—As to the danger which lies in the fibrin, the fact that patients die because they have failed to reabsorb it is enough to point to the necessity of preventing its deposition. The most effectual way, that of completely stopping its supplies, is not, of course, available. This would mean either largely draining the blood away or depriving the blood of its fibrin factor supplies. An attenuation of both these impossible methods is really that which seems to afford the best promise of success. To discourage the local consolidation by diminishing the general supply of the fibrin factors is the end towards which our treatment and diet are made to converge.

5. *The removal of obstructions.*—This is the soul of our tactics. The greater part of our plan of campaign might be described as the carrying out of the principle of clearance and unblocking. The local stagnation of blood and lymph in the lobe affected, whether entirely vaso-paralytic or associated with some fine structural changes, is the first and most important of the obstructions to be dealt with. Short of the acupuncture referred to we cannot treat it locally. A less direct but manifestly active method is that by general vascular depletion and this will presently be referred to as one of our chief resources.

Derivation by the primæ viæ is another and much less expensive form of relief to the circulation. The value of reducing the vascular contents through the bowel cannot be over-estimated and is probably not despised by any clinicians as an instalment of active treatment. The way out must be widely opened and widely used, and a steady lymphatic stream outwards (from the tissues into the veins) kept up not only by the bowel but by the other emunctories, the kidneys and the skin. Diaphoresis and diuresis are scarcely second in importance to catharsis; but we hear less of their being called to the aid of the pneumonic patient. This form of treatment, if applied *à outrance*, might almost compel the reabsorption of any absorbable exudate. But without resorting to extremes we should make an energetic attempt to secure a fair instalment of the desired result.

Diet has an important influence as an aid or a hindrance. Whilst we are endeavouring to unblock the lung by reducing the general bulk and richness of the blood and emptying the lymphatics, the attempt to introduce highly nutritious supplies in constant relays is not theoretically consistent. From a practical aspect it can be shown to be mistaken, as it is liable through almost inevitable fermentative distensions to set up more vascular and lymphatic obstruction than all our measures could avail to relieve. Temporary starvation on a thin fluid diet is the only practical plan for the early stage.

Acceleration of the lymph circulation by cardiac stimulation.—"Take care of the right heart and the left heart will take care of itself" is a maxim recently urged in my lectures upon the Principles of Heart Treatment at the Medical Graduates' College and Polyclinic, the importance of which is brought home to us in pneumonia where the right heart is put to the test Heart treatment may be regarded as the major part of the treatment of pneumonia. The heart is not only the main factor in the resistance of the patient; it is also the chief agent in giving efficiency to our cathartics, to our diuretics, and to our diaphoretics for the work of elimination and reabsorption. Hence the importance of at once lightening its burden and nursing its energy.

AN ILLUSTRATIVE CASE.

Before entering into the details of treatment, I will place before you the brief notes of a case of recovery from double pneumonia of some severity which seems to bear out the view that there may be some use in active treatment, complete defervescence having occurred on the morning of the sixth day and lysis having previously set in on the morning of the fifth day.

The patient, aged 28 years, single, formerly a private in the Queen's Bays and now a fishmonger, was admitted on June 29th, 1904 into St. George's [illegible]
the course o [illegible]
[illegible] s with cough and

perature; more dulness at the right base, which was aspirated without any result Left lung normal A limited pneumothorax was found next day over the lower half of the right chest. This gave rise to no marked symptoms and patient was discharged on July 19th recovered.

REPORT ON THE URINARY CHLORIDES BY MR P. A HAYNE, HOUSE PHYSICIAN.

June 30th (third day of illness three days before crisis)—Specific gravity 1020 No albumin Chlorides: abundant curdy ppt, no diminution Diet "no salt."

July 1st (fourth day of illness two days before crisis)—Specific gravity 1020 No albumin Chlorides abundant fine granular ppt, [illegible]
yesterday "No salt

July 3rd (sixth day of illness day of crisis)—Specific gravity 1020 No albumin. Chlorides less abundant granular ppt, translucent "No salt"[2]

July 4th (seventh day of illness)—Specific gravity 1020 No albumin Chlorides marked diminution since yesterday. Transparent as well as translucent ppt "No salt"

July 5th (eighth day of illness)—Specific gravity 1020 No albumin Chlorides more diminished than yesterday. Ppt very transparent opacity. "No salt"

July 6th (ninth day of illness)—Specific gravity 1020 No albumin Chlorides increased since yesterday Ppt translucent, not transparent. "No salt"

July 7th (tenth day of illness)—*Specimen passed at 6 P.M after having salt for tea at 4 P.M* Specific gravity 1020 No albumin Chlorides same as yesterday "Salt given"

July 8th (eleventh day of illness)—Specific gravity 1020 No albumin. Chlorides much increased flocculent ppt "Salt given"

July 9th (twelfth day of illness)—Specific gravity 1020 No albumin Chlorides normal in amount "Salt given"

REMARKS ON THE CASE

Independently of the effects which seemed to result from treatment this case had features of interest of its own, such as (1) the unusual supervention of delirium on the sixth day during completed defervescence, associated with the history of a former attack of pneumonia with late delirium; and (2) the occurrence of limited pneumothorax after a negative paracentesis at the base for late symptoms of pleuritic effusion. To the treatment, so far as common observation avails, may be attributed at least a share in the following results 1. The short duration of the attack. 2 The early appearance of redux crepitations (fourth day) 3 The presence of watery mucous expectoration on the third day and of some mucus on the fifth day (day of lysis) and the presence of typical rusty expectoration for two days only (fourth and fifth days), though slight tinging of the sputum had been observed on the second day, cough and expectoration finally ceasing on the sixth day. 4 Manifest improvement in the patient's condition after the first day's treatment 5 Complete defervescence (after the lysis) on the fifth day although tubular respiration persisted at both bases until the fifteenth day and rather later than this at the right base, where a recrudescence of dulness occurred without any pyrexia on the thirteenth day, for which the negative aspiration was made. 6 Relatively prolonged absence of chlorides from the urine and their abundant return as soon as salt was supplied in the diet (seventh day) The chief neglected opportunity appears to have been that of better supply of sleep Had this been obtained the delirium might perhaps have been avoided. In other respects the treatment was fairly satisfactory in its general lines and admirably carried out by my excellent house physician, Mr. P A Hayne

THE PRACTICAL DETAILS IN THE APPLICATION OF THE PRINCIPLES OF TREATMENT

First aid.—For the shock of the invasion immediate recumbency, warmth, and a small dose of ether or brandy with hot water are indispensable, and some soothing draught is most desirable, such as ammonium bromide with aromatic spirit of ammonia and from five to ten drops of solution of morphine in chloroform water to prepare the patient by rest for the active measures which cannot be delayed. A dose of calomel is to be administered at once and to be followed half an hour or an hour later with a senna draught.

Cardiac treatment is our next thought Arrangements must be made for the immediate supply of oxygen, which is needed for continuous administration If oxygen is worth administering in desperate states and to the dying why should it be neglected as a profitable adjunct to the active measures of the early stage? Its continuous administration would be a valuable help to the heart against the fatigue inseparable from them It has over the continuous administration of alcohol the advantage of being harmless and of not complicating the alimentary situation There is an apparent contradiction in the two recommendations to diminish the number of the oxygen carriers by leeching and to supply oxygen artificially. But I need not stop to explain that both for lung and heart relief these are converging lines. In connexion with oxygen a practical point is to avoid the glass funnel which has been so generally recommended, as it is the most unsuitable of appliances. The "mask" works better in preventing diffusion of the oxygen away from the patient but it is intolerable to him. The best means is to place the end of the tube itself between the lips or immediately in front of the mouth, or preferably to use Mr. George Stoker's excellent plan of a soft indiarubber nostril-piece which is self-retaining and convenient.

---

[2] No sleep for 36 hours During the morning the patient was somewhat delirious, this increased during the afternoon (the patient endeavouring to get out of bed) and evening until he fell asleep at 9 30 P.M

Bleeding or leeching.—Pneumonia is *par excellence* the field for discussion of the merits of bleeding. But I can only allude to the fundamental question as to whether the bulk and the quality of blood which are needed in the full activity of health are in themselves, or are not, an encumbrance in the prostration of the functions by acute diseases, because this bears closely on the question as to when to bleed. Clinical observation bears out, I think, the ancient belief; but whereas our predecessors both starved the blood and drained it some of the modern teaching urges us to withdraw blood on the one hand and to promote blood making by assiduous feeding on the other. The pain often severely felt on the side of the lesion is relieved so invariably by leeching that the most timid will feel justified in prescribing the latter, particularly as the relief is usually permanent, unlike that from the application of ice or of fomentations. Under the convenient excuse of relieving the pain something more has then been done for the patient beyond the mere soothing of nerve endings. So much impressed am I with this advantage that I make leeching a routine of treatment quite apart from the question of pain. The stronger measure of bleeding from the vein may be required in some cases but it is a more serious undertaking in the sick room and viewed all round is not, perhaps, so desirable as leeching, which is less likely to raise any objection. I rather doubt whether it should be resorted to after consolidation has occurred except as a desperate remedy —a "measure of rescue" from imminent heart failure. The pneumonic patient may well spare a little blood at first; he certainly cannot spare much during his deepening prostration. In this matter, as in others, let us remember to discriminate between the "clinical days" of pneumonia. That which is good or bad on the one day may be just the reverse for the other day. For the present my own position is that abstraction of blood, preferably by leeching, is of great value and of value in proportion to the early date of its employment before the deposition of fibrin. Its function should be to cure rather than to resuscitate, and any loss which it may entail should be inflicted not upon the advanced stages of exhaustion but upon scarcely yet diminished reserves of health. Therefore do not delay making the needful preparations for the application of leeches.

Sweating, already invited by some of the previous measures, might be promoted more actively by a hot-air bath confined to the lower extremities or by De Lancey Rochester's device of a hot mustard foot-bath administered in bed; but internal medication can do what is wanted without any unnecessary fatigue to the patient, and we now come to the question of medication. Its chief aims are diaphoresis, diuresis, antifibrinosis, and absorption. These may be combined in the mixture, which is to be repeated every hour or even every half hour at first to insure rapidly the results in view. I have given antimonial wine, aconite, and green hellebore with none but good results, but simpler remedies may be good enough for our purpose. Leaving aside all so-called vascular depressants and even citrate of potash I now trust to the free use of the ammonium citrate which fulfils concurrently another good purpose. Sweet spirit of nitre may be added to the mixture and the sweating is to be encouraged by warm beverages and one or two doses of gin.

Diuresis.—This object is well served by the agents just mentioned. I doubt whether any stronger ones are needed. As a fact renal permeability is not conspicuously reduced by pneumonia. Our object is gained if plenty of fluid can be passed through the blood and excreted by the skin and by the kidneys without the complication of many drugs. I prefer at present to avoid any possible risks from the use of digitalis and the depressing effects which may attach to the nitrate and to the acetate of potassium. But I am inclined to give further trial to divided doses of calomel, less perhaps on account of its diuretic action than for the sake of its beneficial effect upon absorption.

from fortifying it by the addition of white of egg. As soon as progression towards recovery is established food comes in as the best and only necessary medicine.

Dechloridation.—Under the heading of diet also comes the question of the supply or withdrawal of the chlorides in the food. It has been held that the disappearance of the chlorides from the urine was in part due to their being detained in the fibrin; this if correct would open a question as to the relative value of two opposite lines of diet. First, whether the solidification of the fibrin would be impaired by our diminishing the supply of salt; and, secondly, whether a plentiful supply of salt might not be the means of providing a useful constituent to the blood and restoring the urinary chlorides, and of benefiting the patient whatever the effect on the consolidation might be. For a reply to this question I have not sufficient clinical experience. In this case the practically complete withdrawal of salt from the diet did not seem to interfere with satisfactory improvement, but in other cases I have obtained results even more striking without dechloridation.

Sleep, &c.—After this active work of the first day rest is well earned, though the patient may probably feel relieved rather than fatigued. Just as the first day presents no major risks of heart failure, neither is the first night unsafe for a soothing draught of morphine. The bowels have been relieved; the ways are open. No harm is likely to accrue from the dose and the patient will probably wake with manifest signs of improvement. During the second day the same medicine may be continued. Three grains of quinine in pill or powder will be a useful addition to each dose. Four ounces of alcohol, or perhaps six, will be required but the diet cannot be much increased. The whites of two or three eggs can be added to the whey and the yelks beaten up with gin or brandy. A quarter of a pound of sugar should also be given in the whey. A sleeping draught may be required if the patient is restless. On the third day [illegible]

latter, support is now becoming the main indication. The heart must be fed as well as stimulated. We must make sure that the food is such as will be absorbed. Raw meat juice, strong gravy, maltine, or predigested foods and eggs beaten up should be substituted for the whey, and good milk given in tea or thickened with cocoa. Oxygen must be continued and strychnine frequently injected in anxious cases. In the safe cases the latter may be included in a fresh mixture with carminatives, and iodide of potassium and quinine should also be administered.

Secondary depletion.—The worst cases may not respond to any of these efforts and a second leeching or even a venesection may be indicated. As a preliminary to the latter two single doses of digitalis (tincture and infusion) might be given at an interval of two hours and the venesection immediately preceded by a ten minim dose of a 1 in 1000 solution of adrenalin under the skin.

The further treatment of cases cannot be detailed profitably, as they all diverge more and more. Let me point, however, to the advantage of variety in the stimulant, as I recommend its continuance whilst pyrexia lasts. The "gin always" or the "brandy" may be *ad nauseam.* According to taste or to habit whisky or rum, but specially champagne, port wine, or burgundy may be substituted, at least as an occasional change. The virtues of red wines, particularly when administered hot and with plenty of sugar, are too much neglected in pneumonia which is not a dyspeptic affection. As already hinted, lemons are quite in line with our treatment; I regard them as most valuable in the early stages in the shape of hot lemonade, particularly when their outer glandular layer is also made to yield its precious contents.

VITAL STATISTICS OF THE COUNTY OF DURHAM.—The principal vital statistics obtained in the administrative county of Durham for the year 1904 have just been issued in a concise tabular form by Dr. T. Eustace Hill, the county medical officer of health. For purposes of comparison the corresponding figures for 1903 and for the ten years 1894–1903 are shown in parallel columns. The estimated population for 1904 was 801,100; the birth-rate was 35·6 per 1000; the general death-rate was 18·3 per 1000; the zymotic death-rate was 2·59 per 1000; and the infantile mortality-rate was 162 per 1000 births. Small-pox showed an increased prevalence, the mortality per 1000 of the population being five times as much in 1904 as the average for the ten years 1894–1903.

SOME CLINICAL USES OF IODIC ACID AND THE IODATES.

By WILLIAM MACKIE, M.A., M.D., D.P.H. ABERD.,
LATE PHYSICIAN AND SURGEON TO DR. GRAY'S HOSPITAL, ELGIN.

A FEW years ago I directed attention to some of the surgical and medical uses of calcium iodate.[1] In the interval I have continued to use it both in hospital and in private practice and the results which have since been obtained only serve to substantiate the promise it then gave. Before going on to consider iodic acid and the other iodates it may be useful to summarise the uses to which the calcium salt has up to the present been put.

Its application in fine powder to all cicatrising surfaces—such as after the curetting of scrofulous glands, excision of dead bone, to all incised, lacerated, or contused wounds, and particularly in the case of septic and suppurating wounds—gives excellent results. To leg ulcers it may be applied in ointment spread on lint in strength of from 10 to 20 grains to the ounce of vaseline or other unoxidisable excipient. Out of a large number of cases so treated only once has there been complaint of smarting in the case of male patients, perhaps twice or thrice in the case of female patients, but in no case even where smarting was complained of was any injury done to the tissues. On the other hand, the ulcer was in every case much improved by the application and healing generally took place with unexpected rapidity. Only once has it been applied to a burn in the acute stage when its use was attended with such excessive smarting that it was promptly discontinued. It has never been tried again. Even here it produced no irritation of the tissues. It has now been used in a considerable number of major amputations and excisions of the breasts where it has been applied at the operation in a 3 per cent. gauze. At subsequent dressings irrigation with the warm saturated solution, with or without dusting of the surfaces with the powder according to discretion, and again covering with iodate gauze has been the routine practice. The results have been all that could be desired. Some of the cases were very unpromising but I shall give details of only one which may be taken as a fair example of the power of calcium iodate in preventing sepsis.

A chronic alcoholic, aged 72 years, was admitted into hospital at midnight in a state of intoxication with a compound fracture about four inches below the tuberosity of the tibia. The upper fragment projected through a large ragged wound. Under an anæsthetic the fragments were easily brought into their natural relations, but the soft parts could not be made to meet over them in consequence of evident loss of tissue. The leg was put up on a back splint and at once incased in plaster of Paris with an opening in front opposite the wound for dressing. On the next day, partly from the history given by the patient and partly from inspection of the parts, it was ascertained that there had been an extensive surface of bare and presumably dead bone before the accident and that in this condition it had existed f[illegible] position— [illegible] it was res[illegible] irrigated [illegible] the fine powder being subsequently "showered" in, and for the eight succeeding weeks during which the limb was kept on the splint not a single divergence from a strictly normal temperature was observed. When the splint was removed at the end of that time it was found that there had not been the slightest attempt at union. Amputation was accordingly resolved on and was made through the knee-joint by Stephen Smith's method. The internal condyle of the femur was found to be diseased and was accordingly removed. The case, which was dressed as before described, gave no trouble except for a considerable serous oozing from the wound during the first few days and healed perfectly.

In the case of smaller amputations, such as of fingers or toes, it has been frequently observed that after a liberal use of the powder, repeated two or three times at consecutive dressings, healing takes place under a dry scab without the necessity of further protective dressing. The same remark applies to incised wounds. In not a single case out of a large number of hand injuries received in all conditions of filth has ever the shadow of sepsis been seen where calcium iodate has been used.

---

[1] See THE LANCET, Dec. 29th, 1900, p. 1867.

The warm saturated solution has been largely used as a vaginal douche, and here its deodorant, antiseptic, and astringent effects have probably all, in varying degree in different cases, contributed to the satisfactory results obtained. Perhaps the best—but at the same time not quite unexpected—results have attended its use as a bladder irrigant. For this purpose the warm solution may be used up to the point of saturation. No untoward effects have been observed and a permanent cure has been obtained in a proportion of the cases after a single irrigation. The case of tuberculous bladder which was referred to in a previous paper has been kept under observation since the date of the last irrigation, August 5th, 1900. There has been no recurrence and in the interval not even a suspicious symptom. In another case where tubercle bacilli along with multitudes of colon bacilli were found in the urinary deposits, and where there was a continuous high temperature with general symptoms of some gravity, the warm iodate solution was also used several times. The bladder condition was for the time being complicated with pregnancy, but the patient—now two and a half years after—seems to be in a fair state of health, and the symptoms at least for the present in abeyance. While this case was under treatment it was incidentally observed that a solution of 1 in 1150 inhibited the movements of the colon bacillus.

It was for long in daily use as a mouth wash and gargle, for which purposes it was found eminently efficient as well as cleanly, but latterly, as will be noted, iodic acid has usurped its place in this respect. The saturated solution has also been used as an irrigant in empyema of the chest.

I have also been informed by a dentist of large experience that he has used it for all the purposes for which iodoform or its substitutes are generally used in dentistry and that it is particularly efficient when applied for pyorrhœa alveolaris for which it may be ordered as a dentifrice of the undiluted powder.

It has been found to be all but a specific—in ointment 10 grains to the ounce—for the eczema capitis and other eczemas of infants. As might be expected, the eczema may recur on disuse of the ointment but it always yields to a fresh application. In local eczemas of adults it has also been found of value in some cases, in others not, but it would be difficult to draw any clinical distinction between the cases in which it is and which it is not likely to do good, though I have thought that a specific origin counted for something in a number of the cases. In otorrhœa it is very useful as an irrigant, for which it may be used up to full saturation. It has been used for hypodermic injection into tuberculous joints, after the manner of iodoform emulsion, in only one case—a knee-joint in a boy, aged seven years, who had night starting and elevated temperature. There was bogginess on each of the patellar tendons. About half a drachm of an emulsion (three drachms of calcium iodate to the ounce of glycerine) was injected on two occasions. The temperature became normal, night starting disappeared, and there was at least temporary improvement. In another chronic knee case, probably also tuberculous, in a man, aged 51 years, pus was evacuated by incision and drainage. This was followed by the use of emulsion of the strength indicated. Healing had taken place at the end of five weeks. Injection of emulsion in similar strength was also adopted as the routine treatment in a case of hip-joint disease in a fragile boy, aged seven years—so fragile, indeed, as to preclude the advisability of radical measures—where there existed two large sinuses leading down to dead bone. Whether the treatment contributed in any way to the result may be left an open question, but the sinuses have long healed and the boy is now well and ambulant. Two drachms of emulsion were also on one occasion injected into an abscess cavity of the lung with apparent temporary amelioration of the symptoms.

Medicinally further evidence of its efficiency as a gastro-intestinal antiseptic has been obtained. In a very small proportion of cases it has been found to disagree but the symptoms have not gone beyond a slight temporary discomfort. So far it has only been used in one case of typhoid fever, but in that the results were such as to encourage further trial. The patient was a young woman, aged 20 years, in the middle of the third week of the disease. The morning temperature at the time of the first exhibition of calcium iodate was 102° F. It was ordered in half-ounce doses of the saturated solution diluted with water to be given twice daily and was quickly increased to one and a half ounces three times a day diluted as before. On the second day after its use the diarrhœa, which had been copious, ceased, the temperature began to come down, and on the fifth morning it had reached normal and never rose again. No unpleasant symptoms were observed, though the medicine was continued in the larger dose for a fortnight after a normal temperature was reached. The patient then said that there was a slight metallic taste in her mouth but made no complaint. I may say that I now order iodic acid in place of the iodate for internal use and I should also do so—and have done so—in typhoid fever if I considered any medication on antiseptic lines necessary in that disease.

From a purely economic point of view it may be mentioned that calcium-iodate is produced at two-thirds the price of iodoform.

The success that has attended the use of calcium iodate for the purposes I have noted led me at a later date to try the mother acid—iodic acid—in hopes of attaining even still better results. Generally, it may be said that the acid possesses all the properties of the salt in an enhanced degree. Iodic acid has been used on the continent in solid form or in strong solution as a caustic. It was also at one time thought of as an iodoform substitute but in undiluted powder it was found much too irritant for that. It has, so far as I am aware, never been used for any of the purposes noted below. As regards inhibitory power on the growth of micro-organisms I estimate that as at least three times that of the calcium salt. The following experiment will indicate its power in this direction. Four quantities of the same sample of urine had added to them on March 22nd iodic acid in the following proportions: (*a*) 1 in 25,000, (*b*) 1 in 9000, (*c*) 1 in 4500, and (*d*) 1 in 2500. These along with a control were exposed in unsterilised test-tubes to the atmosphere of the laboratory with the following results: (*a*) began to show signs of decomposition on April 16th, the control having begun to smell badly on the fourth day after exposure; (*b*) showed a few fungoid balls in the mucus at the bottom of the tube on May 22nd, but there was no smell: it had decomposed by June 19th; (*c*) is described as still sweet and clear on July 21st, but some fungoid growth had appeared by August 4th: while (*d*) remained perfectly sweet and clear up to Feb. 15th of the following year, when a single clump of fungoid growth was first observed in the mucus at the bottom but the supernatant urine was still perfectly sweet and clear at the end of the year on March 25th.

In addition to its power as an antiseptic it was found to possess remarkable—in my experience unique—powers as a deodorant and use has mainly been made of it in this direction. With potassium permanganate it compares more than favourably, its power being roughly estimated as three while permanganate is two for equal weights of the salts. It has also been found of service as a deodorant where permanganate quite failed, probably because the chemical action of the two substances is not identical. Iodic acid has the additional advantage of not staining the hands or the tissues, while it is, of course, a much stronger antiseptic than permanganate. Among the uses to which it has been put the following may be briefly enumerated: 1. As an irrigant in the case of a burn in an epileptic female, aged 77 years. The burn was extensive, reaching from above the knee to the ankle and round half the circumference of the limb. On admission it was found put up in a Carron-oil dressing which had not been changed for several days and was in consequence very offensive. There was also deep and extensive sloughing. Iodic acid of the strength of 1 in 500 was used for irrigation and the surface was afterwards dressed with lint wrung out of the solution. The fœtor was discharged at once and no complaint was made of smarting. 2. As an irrigant in ozæna. 3. Also for the same purpose in a patient of filthy habits who had infected an amputation wound of the thigh with the colon bacillus. 4. For placing in the recipient vessel in the case of a most offensive urine—without exception the vilest ever experienced—in the case of an old man who had long led a catheter life. 5. As an irrigant in empyema of the chest, also in strength 1 in 500. 6. Lint wrung out of 1 in 500 solution was used in the first instance as an application to clean and to deodorise two very offensive leg ulcers in an ataxic female, aged 75 years, and proving efficient and non-irritant was continued till perfect healing had taken place. 7. In same strength as a mouth wash in a case of recurrent and inoperable epithelioma of the mouth and cheek. 8. As a vaginal douche in a case of inoperable cancer of the uterus and vagina. In all of these cases the solution of 1 in 500 proved efficient beyond expectation. As regards the last two cases no one knowing the fœtor attending such cases would probably believe without trial that the results obtained were possible. For months both were kept perfectly free from the slightest indication of fœtor. 9. During a year's experience in the local Fever Hospital iodic acid was the all but exclusive substance, in strengths up to 1 in 300, used for applications to the throat in diphtheria and scarlet fever, while it was in general use as a mouth wash in 1 in 500 and was found particularly useful for the latter purpose in cases of typhoid fever. 10. Internally I have frequently ordered a drachm of 1 in 100 freely diluted with the happiest results for gastro-intestinal sepsis or fermentation. For this purpose I consider it to be a more elegant prescription than the ordering of one or two drops of tincture of iodine in solution. No untoward symptoms have been recorded after its use. 11. It was given internally in two cases of typhoid fever. Both were of exceptional severity but it was credited with checking excessive diarrhœa in one of them after other treatment had failed. The case, however, which was complicated with multiple abscesses all over the body, eventually proved fatal. 12. The last two operations which I performed in Dr. Gray's Hospital—an amputation of an arm through the upper third of the humerus and an excision of a breast—were carried through on antiseptic lines with iodic acid for the whole technique, for disinfecting the skin, the instruments, &c., and for irrigation at subsequent dressings, calcium iodate gauze being used as before. The results were unexceptional.

The iodate of zinc has also been used. It is soluble at ordinary temperatures to slightly over 2 per cent. and contains about 61 per cent. of available iodine. I have found it useful where a stronger solution of calcium iodate than the natural insolubility of that salt admits of being prepared appeared to be indicated and it has been used in various strengths up to full saturation in the following cases: (1) for injecting chronic sinuses left after curetting tuberculous glands; (2) in the same way in disease of phalanges and metacarpal [illegible] (3) for disinfecting the [illegible] suppurating glands of the [illegible] abscess cavity of the p[illegible] offensive otorrhœa up to t[illegible] the results were excellent in all I may say that I was particularly pleased with its action under (2) and (5).

Subiodate of bismuth has also been used. The samples prepared by me, as well as those prepared for me, showed about 48 per cent. of available iodine. It is a very fine white powder in consistency very like the carbonate of the same base. It has been used with unexpected, but perhaps not always permanent, results in lupus. Three cases in all have been treated.

The first case was that of a female, aged 28 years, who had had lupus since nine years of age. The parts affected were both cheeks, the upper lip, and both alæ nasi. The anterior nares were occluded from cicatricial contraction. There was a discrete patch of the size of half a crown under the chin. The case had been repeatedly curetted in Dr. Gray's and other hospitals—14 times in all, she said. She was admitted on Feb. 11th, 1901, and the treatment, which was at first purely tentative, consisted in the removal of all crusts and dusting the surface with either calcium iodate or bismuth subiodate. A comparative test was made between the two substances, calcium iodate being applied to the general surface of the cheeks and upper lip and the bismuth salt to the patch below the chin. It was soon observed that the latter gave the better result and the calcium salt was thenceforward entirely discarded. On March 12th, in order to accelerate the action, a general curetting was done under [illegible] iodate was con-[illegible] of treatment was [illegible] every other day, the surface was irrigated with a solution of iodic acid (1 in 500), and while still wet it was dusted over with the subiodate. From time to time, as seemed to be indicated, small corners of the affected area were curetted under chloretone and probably the whole surface would in time be gone over in this way. At the end of ten weeks from the date of admission she left the hospital with the whole surface healed over. The disease was well in hand some weeks before this but the patient was kept longer in hospital for the purpose of opening out and keeping dilated the anterior nares. It is understood that recurrence took place about two years afterwards, which was certainly the longest period of remission since the start of the disease.

The second case was also that of a female, aged 40 years, who had been the victim of lupus for ten years. Curetting with various subsequent applications had been made on several previous occasions and for a time I believe she had thyroid extract with apparently temporary benefit. She was admitted on May 20th, 1901. She left the hospital on June 29th. No general curetting was done in this case but the piecemeal curetting under chloretone was carried out as before. She left us to undergo the Finsen treatment at the London Hospital. On her return after five months' treatment she was seen by me, but beyond the fact that the skin was whiter, as would naturally be expected, there was little advance on the condition in which she left us.

The third case was that of a boy, aged 15 years, who showed a spot of about the size of a crownpiece on one cheek. When he left the hospital at the end of six weeks it was entirely healed. It is not known whether there has been any return.

In a very chronic skin affection of the face in a female, aged 35 years, which was probably of the nature of lupus erythematosus and which had resisted various applications, bismuth subiodate ointment, 20 grains to the ounce, was also found to have a very beneficial effect.

The subiodate has also been used as a dusting powder in a fairly large numb[illegible]ulous glands. In the less [illegible] scab was found to be the [illegible] I think less frequently, has also been noted where calcium iodate was applied. After a fairly extended trial in such cases I am inclined to prefer the bismuth salt, though results are certainly good with either.

No irritant or other unpleasant effects have at any time been observed after its use.

Mercuric iodate has been used on the continent but so far as I know exclusively for the hypodermic medication of syphilis. It contains about 46 per cent. of available iodine. This salt is likely to prove a general antiseptic of equal efficiency with the perchloride or iodide. With common salt it is soluble up to 2 per cent. or more. This would facilitate its use as a general antiseptic as it would make a supply easily portable in concentrated solution. It has the advantage over the perchloride of containing weight for weight something less than half as much mercury and of striking as an antiseptic with both ions of the salt. Comparative tests also show that it deposits mercury less readily on steel or metal instruments than the perchloride, its power being exerted rather in the direction of oxidation of the steel than of deposit of mercury. Further, what deposit does take place is readily wiped off. The following tests of its restraining power were made. 0·020 gramme of the salt was placed in 100 cubic centimetres (1 in 5000) of unsterilised, undiluted, ascitic fluid in an unsterilised flask. It readily dissolved on shaking. Along with a control it was then freely exposed to the air. The former had decomposed by the end of a week, while the fluid to which the iodate had been added continued sweet and limpid up to the end of the fifth week. With 0·030 gramme in 300 cubic centimetres (1 in 10,000) in like manner it did not begin to decompose till the middle of the fourth week. Iodic acid in the proportion of 1 in 1000 gave a result similar to the stronger solution, from which it may be inferred that mercuric iodate shows roughly five times the restraining power of the mother acid.

Mercuric iodate has been put to the following clinical uses. A man, aged 28 years, was admitted into hospital with a pronounced sycosis over all the hairy parts of his face but the right cheek was very much worse than the left. Before admission he had been treated with all sorts of applications, calcium iodate in ointment among the number. His teeth, which were carious to a degree, had all been extracted without result. On admission mercuric iodate in 20 grains to the ounce of chrisma was ordered for application to the right cheek which, as stated, was by far the worse, and unguentum vaselinum plumbicum to the left, the beard being kept closely shaved. By the end of a month the difference in the effect of the two applications had become so marked that the patient begged to be allowed to apply the mercury iodate to both cheeks which was accordingly done with complete cure in ten weeks from the start of the treatment. There has been no recurrence.

In eight consecutive cases of tinea barbæ, some of them very bad, an ointment of the same strength was ordered and has given most gratifying results. Several of them yielded after two or three applications of the ointment. All of them vanished with what for the disease in question would be considered quite surprising rapidity. From its solubility in presence of sodium chloride one would infer considerable penetrating power and to this in part the results obtained are probably due.

On the whole it may be said that iodic acid and the iodates come quite up to the expectation formed of them on theoretical grounds and actual trial shows that they may be made of extensive clinical use.

Elgin.

EXPERIENCES WITH IODOFORM BONE PLUGGING.[1]

BY HOFRATH PROFESSOR VON MOSETIG MOORHOF,
FIRST SURGEON TO THE ALLGEMEINES KRANKENHAUS, VIENNA;
AND
B. SEYMOUR JONES, F.R.C.S. ENG.,
LATE HOUSE SURGEON AND CLINICAL ASSISTANT IN THE EAR DEPARTMENT, ST. THOMAS'S HOSPITAL.

THE material which is used for bone plugging (*Iodoformknochenplombe* as it is called) consists of a mixture of 60 parts of the finest pulverised iodoform and 40 parts each of spermaceti and oil of sesame—a compound which at the ordinary temperature of a room forms a stiff yellow mass. At 50° C. (112° F.) the substance becomes fluid, and on allowing it to stand and cool the oily constituents separate above whilst the heavier iodoform sinks to the bottom. In order to obtain a homogeneous emulsion, the substance, after being melted by warming, must subsequently be well shaken up and then it is ready for use. Hence, for this object, it is necessary that the vessel containing the "plugging" be not quite filled, as then shaking up the contents would be practically impossible. Wide cylindrical glass tubes, in other words large test tubes, the orifices of which are closed with glass or rubber stoppers, proved to be best adapted for this purpose. Filled to about two-thirds they can be kept in stock any length of time in a convenient form.

When Professor Moorhof commenced his studies and researches on bone cavities five years ago,[2] an iodoform paste of the consistency of putty was used, but soon the conclusion was reached that to achieve success a hermetical and perfect filling of the cavity was essential, and this desideratum could only be attained by pouring in a fluid substance which solidifies *in situ*. The solid mass must be in contact with, and adhere to, every portion of the walls, penetrating every fissure and interstice, filling the cavity completely. Hence it is a *sine quâ non* that the cavity should be dry. Blood or fluid used for syringing would prevent the intimate apposition of the "plugging" with the walls. *Mutatis mutandis*, therefore, the rules for stopping teeth apply here, only the shape of the cavity is of no consequence. For drying the bone cavities hot air is employed and applied with the drying instrument of proved value which Dr. Silbermack[3] has described.

As it is obvious that every surgeon has not electrical power at his disposal, a very simple contrivance has been devised by means of which sterile, cold dry air can be blown into the cavity. Ordinary air is driven by means of a double rubber bag or bellows—in the latter case manipulated by the foot—through formalin solution and then through calcium chloride. After syringing out the cavity with a 1 per cent. formalin solution the drying should be continued until the wet glistening walls appear dull, a proof of their freedom from moisture. Chisels of various form and size, bone forceps, and sharp spoons are employed for the removal of the bony walls; if electrical power can be commanded rotation saws and drills, such as Dr. Silbermack has specified, are recommended.

It is an absolute *sine quâ non* that the walls of the cavity to be plugged should contain no diseased tissue and should be perfectly aseptic. Whereas the last stated postulate is never attainable with certainty through antiseptic measures and only a relative asepticity of the wound can be anticipated from any precautions adopted, the injunction is given to plug only such cavities as have had their walls freshly excavated under antiseptic precautions immediately before the filling or the plugging.

The plugging material which is poured in—it is recommended to pour slowly—sets *in situ* in a few minutes; the superficial soft parts can then be united after a previous complete arrest of all bleeding by ligation. No especial drainage is required, for well-plugged and filled cavities obviously neither bleed nor discharge. Existing fistulous tracts in the covering soft parts amply suffice for the escape of the insignificant amount of lymph which the soft parts secrete; if no sinuses are present it is sufficient if the sutures are not inserted close together; the scanty secretion leaks away freely through the interspaces. If one cannot be persuaded to dispense with drainage no tubes at least should be used; a narrow thin strip of oiled silk folded fanwise may be inserted between the lips of the wound. The protective dressing should not be regarded as a pressure pad; circulatory disturbances ought to be avoided.

The secretion of the wound is invariably of a "lymphoid" character and corresponds to the number and extent of divided lymphatic vessels. In a case of sequestrectomy of the tibia in which the periosteal skin-flap had grown adherent to the floor of the matrix by primary intention a form of lymphoid tumour appeared in the third week. The softs parts over the site of the plugged cavity were raised as a fluctuating swelling. The painlessness and the lack of local inflammatory symptoms and of any rise of temperature suggested the above diagnosis. A small incision was made and serum escaped. The gradual elimination of the plugging material, associated with large defects of the skin, is also accompanied by serous, never by purulent secretion, assuming naturally that the after-treatment is aseptic.

The iodoform bone plugging or filling substance, which name many consider denotes it more correctly, has only a provisional sojourn in the wound cavity; it may be either pressed up and expelled by the new connective formation, which brings about the final obliteration of the cavity as the latter grows into the mass; or it may be absorbed and consumed if no channel of escape exists, owing to a primary healing of the intervening superficial soft parts. In the latter event iodine can be demonstrated in the urine during the course of the healing of the wound. Hence it follows that the absorption of the filling substance by the granulations naturally takes place extremely slowly and constitutes the reason why there is no danger of intoxication, for such an event can only ensue through the sudden absorption of considerable quantities by the organism; the large size and extent of the wound cavity are therefore no contra-indication to plugging or filling. Iodoform bone plugging thus protects the granulations from septic disintegration, which must necessarily occur with the persistence of the cavity and be maintained as the suppuration. The "locum-tenens" preserves the entire granulation; nothing thereof is lost and organic restoration is accomplished more speedily and completely. Defects in the bone disappear and the normal shape and size of the bone are restored in a given time. Concerning the question as to in what way—viewed from a histological standpoint—the plugged cavity becomes filled up with bone tissue: first, the close examination of the skiagrams is able to throw some light; and secondly, the circumstance that the filling substance is gradually absorbed. The latter event can only occur through the action of granulations; consequently granulations must first sprout from the walls of the cavity. The production and gradual growth of bone tissue are effected by a primary formation of new connective tissue. Subsequently definitive osteoid tissue is formed from this by the deposition of lime salts. Hence, in a skiagram the immediate neighbourhood of the disappearing plugging material appears lighter in colour, resembling a halo. This lighter zone grows gradually darker, the transformation advancing with the new bone formation, so that in the course of time the bone shadow extends uniformly throughout the area. The restoration of the bone is then accomplished. It has been derived from granulation tissue by the secondary deposit of lime in an originally connective-tissue base, simulating therefore the phases in the formation of callus. The question has, however, no practical importance; its only interest lies in the fact that a new formation of bone tissue generally ensues after the introduction of the iodoform filling substance and that this fact has been clearly established and can at any time be checked by the use of the Roentgen rays In this connexion Dr Silbermack has made extensive investigations with animals since the beginning of 1903, the result of which he will duly publish

---

[1] Deutsche Zeitschrift fur Chirurgie, Band lxvi., S. 689, 1904.

[2] S. Hackmann: Wiener Klinische Wochenschrift, 1901, p. 537.

[3] Deutsche Zeitschrift fur Chirurgie, Band lxvi., S. 589.

By means of the Roentgen rays the decrease of the plugging material can always be verified, this proceeds hand in hand with t

in the skiagr

required for t

variable and

cubical extent of the cavity For example no trace of the plugging material which was used to fill a necrosis cavity in a tibia approximately of the size of a hen s egg, was discernible in a skiagram after the lapse of a year The bone had regained its normal shape The patient was discharged *fit for work six weeks after the* operation with a completely healed wound in the soft parts

Should defects remain in the superficial soft parts after the operation either at the site of an old cicatrix which has contracted or in the situation of a former sinus—in short if *the closure of the* wound is not perfect—it is found that a portion of the filling substance is extruded by the granulations and cast off in the shape of small fragments To all intents and purposes however, the outcome is the same whether the whole is absorbed or is partly absorbed and partly eliminated the material performs the function of a "locum tenens" preventing suppuration and loss of the granulations, it persists until the organic restoration of the cavity is accomplished, whereby healing proceeds more simply and pleasantly for the patient and decidedly quicker

Ill effects of the operation, such as intolerance of the plugging and a subsequent necessity for its removal Professor Moorhof has never witnessed and his experience extends over some 220 cases Similarly, he has never seen symptoms of iodism or the so called "cures with sinus formation which are really no cures at all but are only "whited sepulchres in the depths of which the process of *disease smoulders and after a longer or shorter interval* awakes afresh During the first day or two after the operation an increased frequency of pulse and a slight rise of temperature are sometimes observed which as a rule completely subside on the third day

At the commencement of his studies Professor Moorhof employed iodoform plugging solely for the filling of cavities in bone, subsequently, however, he extended its application also to cavities the walls of which were not exclusively constituted of bony substance but were bounded after the removal of smaller bones partly by soft parts partly by bone, cartilage &c, as for example, the cavity resulting from extirpation of the calcaneum, after resection of the wrist, &c—invariably with the same gratifying result If one stops to consider that the iodoform bone plugging is only enlisted to serve as a temporary stop gap and solely for the obliteration of the dead space then the justification for the procedure will be appreciated and understood The indications for the use of the plugging are therefore of tolerably wide latitude and their number is by no means exhausted

The principal class for plugging comprises the common osteomyelitic affections and tuberculous disease of the articulations and bones The acute *osteomyelitis* occurring in young individuals and ushered in with severe symptoms which most commonly begins at the epiphyseal end of the diaphysis and pursues its course with violent local septic and general symptoms is obviously not suitable for the operation since asepsis is unattainable Here one rests content

soft parts exposure of the

subsequent removal of the

with antiseptics and the

with free drainage It is only the chronic cases of circumscribed osteomyelitis which are adapted for plugging as for example the strictly limited osteomyelitis granulosa which in certain circumstances gives rise to an encapsuled abscess in the bone—a condition but rarely found with us Another chronic condition where plugging is indicated is when a cavity is formed as the result of acute necrosis

The operation for necrosis is conducted in the following manner The affected limb—as a matter of fact most frequently the lower extremity—is first maintained in an elevated position for some minutes when an Esmarch's rubber band is applied on the proximal side The preliminary elevation should deplete the extremity as far as possible of blood If this precaution is neglected and the band is applied without *previous elevation of* the limb drops of venous blood exude for a considerable time from the Haversian canals of the cavity after the excavation has been prepared—a troublesome circumstance which delays the introduction of the plugging Limbs well depleted before applying the constricting band scarcely ever manifest these undesirable "*stillicidium e parietibus*" But there are cases in which the application of the tourniquet is *impracticable*, for instance foci of disease in the trochanter the neck of the humerus the ilium or the thoracic skeleton The arrest of bleeding is then very tedious and often requires great patience. Peroxide of hydrogen (from 3 to 5 per cent) and pressure tampons are employed in these cases, stronger solutions of peroxide cauterise and do not work better or quicker Adrenalin may also be tried The focus of disease in the bone must be exposed to the greatest possible extent in order that the operation may be conducted with precision and ease

In the leg particularly for the tibia, almost exclusively curved incisions are made, which define a flap with the base directed to the inner or outer side This long periosteal skin flap is detached and raised directly from the bone, including the whole width of the anterior surface, in such a manner as to expose its entire aspect The openings of the sinuses are for the present not interfered with and the corresponding defects in the skin are raised with the flaps, here the knife may assist the elevator *The cloacal canals in the periosteal* bone are disregarded but perhaps may be used for probing Exposure of the cavity in the bone is effected independently of them by the removal of a correspondingly large segment of the anterior wall This section of the bone is readily accomplished with a rotatory electric saw, more slowly with chisels especially if eburnation is present When the disease is sufficiently exposed any sequestra present are removed and the whole of the granulations and purulent substance in the cavity are carefully scraped away with sharp spoons until nothing more meets the eye than smooth hard bone Care should be taken that concealed recesses in the walls of the cavity are not overlooked Finally, a hollow chisel as a gouge was often employed, better still and more effective is the use of a stout olive shaped burr, rotated electrically

In cases of necrosis of the femur the exposure of the bone is effected by means of a large skin muscle periosteal flap which is cut from the outer side of the thigh with its base upwards and its breadth corresponding to half the circumference The lower rounded margin of this extensive flap must be carefully planned with respect to the limits of the suprapatellar bursa The rectus femoris is partially, and the vastus externus is completely, divided the biceps remaining intact the incision courses along the anterior border of the latter muscle This broad and necessarily long, bulky flap is elevated together with the periosteum from the bone which is laid bare throughout its greater extent The cloacal aperture as is well known is most commonly located on the posterior aspect of the femur No attention is paid to it at this stage but a large window is sawn or chiselled out of the cortex of the external surface of the bone Free access is now afforded to the cavity which is thoroughly cleaned out and new walls are fashioned When the

it often necessitates

spoons inside the

cavities frequently

nger It demands patience and perseverance and the operation should be performed quietly and carefully When this task has been conscientiously performed and the cavity has been well syringed out and dried the plugging or filling may now be proceeded with The patient lies in the horizontal position the wide aperture of the cavity being situated in the external wall of the cortex The cavity itself extends upwards to a varying height towards the healthy marrow and descends on the other

As it is essential to ol

plugging material each co

turn be so disposed that the fluid mass can flow in as the

first tilted well

r

to hang down

o

now situated

undermost and the material can be readily poured in completely filling the whole lower segment It is now necessary to wait for some minutes with the patient held in this awkward posture until the filling substance is firmly set

The position of the leg is now reversed and the limb is elevated, so that what was the upper recess is now the lower; this is then filled. After a repetition of the delay to allow this material to set the filling of the cavity is completed with the limb on its side in the horizontal position. The everted, bulky, skin-muscle-periosteal flap is sutured in its original position again and heals readily by primary intention. Before suturing the flap in position all existing sinus tracts are thoroughly curetted and then left to serve for drainage. The extremity is next freely surrounded with dressings and the constricting rubber band which has remained applied until this stage is removed. Secondary hæmorrhage has never been met with. The dressing is left intact for at least a week and is usually taken down on the tenth day, when the sutures in the soft parts are removed. Subsequent dressings are also changed at weekly intervals. *Mutatis mutandis*, the same method of operation is applicable to tuberculous osteomyelitis, including the cases of affected phalanges. These are often completely extirpated, the periosteum alone being preserved and the resulting cavity plugged.

A special section is required for that disease which is of such frequent occurrence among the affections of joints—namely, tuberculous arthritis—with or without associated caries. Professor Moorhof maintains the view that tuberculosis of a joint should be dealt with by operation as soon as the diagnosis is clearly established, irrespective of the age of the patient. The so-called conservative treatment with retentive apparatus, venous congestion, injections into the joint, &c., is so much loss of time and ought only to be appealed to if the patients or their relatives refuse operative interference. Local tuberculous disease is well recognised to be capable of causing general infection. Why, then, leave in the body a source of an ever-possible extension or at least of deleterious influence on the organism? Spontaneo cure—that is, a cure effected without operative interferen is a very tedious business and often beyond the means poorer classes. After years of treatment joints of ostensibly heal, frequently with deformities and co and tolerably often with a legacy of sinuses. several cases of children with apparently heal knee-joints it has been necessary to operat undergone many years of treatment—th system of the limb atrophied, the knee and the joint partially dislocated, some externally rotated. Resection had to be pe cases to straighten the otherwise useless e encapsulated caseous deposits were found, somet condyles of the femur, sometimes in the head of ia and in the patella; and furthermore, tuberculous remnants of the capsule in the midst of the cicatrised and obliterated suprapatellar bursa. Is one, therefore, correct in speaking of healed tuberculosis of the knee-joint in such cases?—and such conditions are not unseldom found; yet these cases are numbered among the apparently successful cures, often merely because no sinuses exist. Is not any accidental injury capable of rupturing the encapsuled infectious deposit and occasioning a general infection of the body, or at least a local relapse? Every tuberculosis deposit in the organism is potentially evil; its removal is accordingly imperative, and should be effected with the same conscientious thoroughness that is displayed in the extirpation of a malignant growth. All morbid tissue must be eliminated and no vestige of it should be left behind in the field of operation to which the eye and hand can obtain access and exterminate.

But the affected limb must be considered also with a view to its future utility and in children, therefore, the epiphyseal cartilage should be preserved in order that the integrity of growth should remain unimpaired. Resection of a joint should only be undertaken if all these prescribed conditions are conscientiously borne in mind and respected. The greatest pains should be bestowed on the thorough extirpation of tuberculous deposits which are invariably present in the joint capsule, the ligaments, and their surroundings. It does not suffice to remove the soft fungoid granulations by simple curetting; as much as possible of the whole capsule must be extirpated in continuity by means of scissors and scalpel and no remnants left—just as one has thoroughly to remove tuberculous tendon sheaths and synovial pouches. Iodoform certainly possesses anti-tuberculous properties, as oorhof maintained 20 go; but a know-

The foregoing represents Professor Moorhof's view upon the true conservative treatment, for this alone in advanced cases is capable of preserving the patient from the subsequent necessity of a mutilative operation, the loss of a limb, general infection of the organism, and marasmus.

OPERATIONS RECOMMENDED.

For the surgical removal of tuberculous disease in a joint the most important factor is the freest possible exposure of the field of operation. Hence those methods of operation or lines of incision are the best which accord most completely with this postulate. One should never work in the dark; all diseased tissue must be thoroughly extirpated to obtain a satisfactory result.

Wrist-joint.—The hand, having been first disinfected and rendered anæmic with bandage and tourniquet, rests secured with its palmar surface on a firm support. A large dorsal skin flap is then marked out with the base directed towards the wrist; the free border of the flap, which is cut with a somewhat convex margin, embraces the whole width of the dorsum and extends as far as the bases of the metacarpals. This large flap with parallel margins is dissected up from the subjacent tendon sheaths and turned back on the forearm, double ligatures being applied to the superficial veins as they are divided. The individual tendon sheaths are next laid open and the tend are exposed. These should be separated one after a order to render the deeper-seated parts accessibl lls of the posterior tendon sheaths, which ergone tuberculous degeneration, are syst by means of scissors and rat-to rsal surfaces of the carpal bones parately seized with a stout bone a pair of curved sharp scissors, e latter into the interstices. In this the carpus are successively removed f the pisiform and os magnum, the always, and the latter if possible, pre- of the tendons remain untouched. If one other of the extensor tendons should be injured it must epaired by subsequent tendon suturing. After the removal six or seven of the carpal bones access is obtained to the palmar segment of the capsule of the joint, which when found to be affected with tubercle is thoroughly extirpated. If the bases of the metacarpals prove to be carious the diseased ends are resected; if a tuberculous deposit is discovered in the epiphysis of the radius it is cut out from the surrounding healthy bone. When the part has been washed clean with formalin solution and the cavity in the soft parts has been dried the hand is approximated to the forearm, placed in slight dorsal flexion, and the somewhat diminished gap is filled with plugging material. This is poured in between the temporarily separated tendons and the skin flap is sutured in position. Pre-existing sinus openings serve after careful curetting for the escape of the scanty secretion of the wound. Thin, bluish, undermined skin is best removed if feasible. In the absence of sinuses a thin strip of oiled silk may be inserted quite lightly on one or both sides of the flap. Starch bandages, reinforced with narrow strips of thin veneered wood, secure the immobilisation of the hand in slight dorsal flexion. The first dressing usually is done from ten to 14 days afterwards. Preservation and retention of individual carpal bones are not recommended when the disease is at all extensive. If this is done very often foci of disease are left behind in the interstices of the little joints, which, as we know, intercommunicate, and hence the occurrence of relapses and the so-called "healing with sinus formation."

The results of total resection of the wrist-joint, performed according to the above-described technique, are excellent. Although somewhat shortened a moveable and comparatively good useful hand remains. Care should be taken that the posterior annular ligament is preserved as it secures the extensor movements of the fingers. By this method I have succeeded in retaining useful hands, even when the bases of the metacarpals were affected by caries and the tuberculous process already established between the palmar tendons. These are tedious operations truly but are rewarded by preservation of the function of the fingers.

Elbow-joint.—In resection of the elbow-joint on account of tuberculous disease the method of Victor von Bruno is used with provisional sawing through and eversion of the olecranon in the flap. This method alone affords satisfactory access to the interior of the articulation. A transverse

---

substance has set a smal
each deposit as a protection, which is covered with dry gauze and held securely applied by the assistant. The upper cartilaginous portion of the olecranon, which in most *cases is found to be carious, is then sawn off. Next,* Esmarch's bandage is relaxed, the bleeding arrested by ligation, the pieces of oiled silk removed, the temporarily dislocated olecranon wired, and the wound closed by sutures,
[illegible] l on the inner side. The dressing
[illegible] n of the elbow almost at right
[illegible] reinforced with strips of wood.
[illegible] after 12 or 14 days, sutures and
drain being removed. Passive movements are then begun. The bone suture has never caused me any anxiety; the silver wire becomes incorporated quietly and remains visible in skiagrams. As the aim is to obtain a new joint at the elbow one need not be too exact in the amount of bone removed and immobilisation of the resected joint must not be protracted too long. Only the first dressing at the operation fixes the elbow, the second and following should merely serve to cover and to protect the wound, and ought not to interfere with movements. In consequence of the difficulties attending the filling of the cavity, resulting from resection of this articulation, Professor Moorhof contented himself with merely rubbing boiled iodoform power over its walls.

Shoulder-joint.—Since in tuberculous disease of the shoulder-joint the thorough extirpation of the diseased capsule and possibly affected bursæ in connexion with it, is of prime importance, the customary long anterior in-
[illegible] nded; decidedly preferable
[illegible] flap. After displacing the
[illegible] end of the bone is sawn off
[illegible] e extirpation of the capsule
[illegible] up with plugging material,
[illegible] o his side. A short drain is
[illegible] refully sutured in position.
[illegible] operation described in the
following text, and which is regarded as typical, has given complete satisfaction in 15 cases; it affords the widest accessibility to the foci of disease which it is possible to obtain and transforms, with a little practice, the otherwise difficult operation into a comparatively easy and safe one.

[illegible]

bends in a wide arch
and is conducted ba
point behind the other malleolus; at the inner and outer malleolus the incision is made above the course of the posterior tibial artery and the peroneal tendons respe [illegible]
The broad and convex flap thus marked out is raise [illegible]
the extensor tendons for a short distance and the she [illegible]

[illegible] middle. In the
[illegible] *from the neigh-*
[illegible] the foot and its
[illegible] are applied, and
[illegible] n the superficial
fascia have previously been secured and ligatured. The entire soft parts of the dorsum are now dissected up along the astragalus and thrown back centrally in the form of a flap. During this step the anterior wall of the capsule of the ankle-joint is usually severed, as the dissection proceeds backwards, the joint being opened. The lateral ligaments are then divided, internally the deltoid ligament, externally the three bands which extend from the outer malleolus to the astragalus and the os calcis; the foot in consequence hangs quite loosely, the whole astragalus facing the sitting operator. The opening of the astragalo-navicular joint comes next and the astragalus is excised by a few snips of the scissors. Extirpation of the posterior wall of the capsule is readily effected after the removal of the astragalus but care must be taken to avoid severing the tibialis posticus tendon, likewise the tendons of the peronei should not be injured. Excision of the tuberculous tissue in the sinus tarsi completes the operation. After the cavity has been syringed out and dried the foot is approximated to the empty socket formed by the lower ends of the tibia and the fibula and the intervening gap is filled up with *plugging material; the ends of the tendons are afterwards* re-united by using the silk check-threads. The skin is drawn together by sutures, a short drain is introduced if no sinus openings exist, the dressing being applied and retained with starch bandages in which strips of wood are incorporated. In order to prevent the escape of the fluid plugging material through the lateral angles of the wound it is advisable to close them beforehand with a few sutures. Accordingly stitches are first inserted in the submalleolar regions and then, *after turning the flap back and temporarily* separating the sutured tendons, the material is poured into the cavity, allowed to set, and the closure of the wound is subsequently effected.

The astragalus is removed in all circumstances, otherwise thorough extirpation of the capsule would be impracticable: a *sine quâ non* for success. In one case, for example, after the completion of this step it was found that the os calcis was also diseased. It was necessary therefore to proceed with the excavation of the calcaneum *from above until only* a thin shell of the cortex remained. Primary healing and gradual regeneration of the calcaneum ensued, despite the presence of the plugging substance. In another case, a carious focus was found in the lower epiphysis of the tibia which was extirpated and plugged. In all the 15 cases operated upon, up to the present, healing has occurred with useful extremities and, moreover, with the formation of a new joint, hence with moveable feet. The shortening amounted to some two centimetres. Concerning the treatment of caries of the tarsal bones situated in front of the line of the mid-tarsal joint the method employed is the same with the only modification that the base of the flap is displaced further forward and its free border extends as far as the posterior third of the metatarsal bones.

Knee-joint.—In the operation of resection of the knee-joint so frequently undertaken the transverse incision across the patella and section of the latter devised by von Volkmann are employed. A short *incision is first made which* penetrates to the patella and corresponds to its transverse median diameter; this is then prolonged on both sides in a wide arch to the upper contour of the condyles of the femur. The patella is divided by the saw and both halves are everted in the flaps after division of the capsule and lateral ligaments. The upper half of the bone is now retracted by means of a sharp bone hook and the entire suprapatellar
bursa is thereupon dissected awa
tendon and inner surface of the
[illegible] forceps and scissor
[illegible] of all tuberculous tissue, so
[illegible] operation. No vestige of it
[illegible] ndons and muscular fibres
ought to be visible. If a rupture of the bursa has already
[illegible] upper part and the tuberculous process has
[illegible] cular tissue, the original incision
[illegible] he infiltrated parts dissected away
[illegible] *from the healthy surroundings.*
[illegible] abscess into the popliteal space
and its [illegible] e muscles of the calf may prove a
very disagreeable complication, yet with patience and

circumspection even this difficulty may be overcome. Accompanying sinuses may be excised. Attention is next directed to the lower segment of the patella; this is drawn downwards and the lower and anterior portion of the capsule is dissected away until healthy tissue is reached. The joint is now bent and the crucial ligaments are divided. The division of the latter is effected by directing the knife towards the inner condylar notch in order to avoid wounding the popliteal vessels inadvertently. The joint now gapes and an excellent view can be obtained of the diseased posterior wall of the capsule and the articular cartilages of the bones which usually exhibit areas of erosion.

Professor Moorhof then proceeds according to the following rule, which is applied in all cases to children—to adults if the bones do not appear much altered—viz., to perform the operation with a stout knife and to remove therewith the cartilage piecemeal from the end of the tibia and the femur. If one or more tuberculous deposits are found in the femur or head of the tibia, as is so frequently the case, they must be cut out of the healthy bone—a mere curetting with spoons does not suffice—and then filled with plugging material. In adults with extensive destruction of the bones concavo-convex slices are sawn off from the ends of both components of the joint, as Helferich recommends, but with children the saw is never used, since the integrity of the epiphyseal cartilage is of vital necessity for unstunted growth. The posterior wall next receives attention and is extirpated as far as possible entire; here, again, the dissection should be persevered with until healthy tissue appears in order to insure the removal of all disease. This excision of the posterior capsular wall is very circumspectly carried out with scissors and rat-toothed forceps and requires a practised hand in view of the fact that the popliteal vessels, particularly the artery, lie immediately behind the diseased capsular wall. Attention is also directed to the niches behind the condyles and the tent-like diverticula of the capsule in this situation, which must be systematically extirpated, as they invariably conceal masses of tuberculous tissue. In adults the saw is employed and it is advisable to remove only thin sections of bone with a sharp fret saw, concave on the tibia, convex to the end of the femur, accord-to Helferich's method. There is no advantage in sawing off thick slices of bone; it is only detrimental to the patient by producing greater shortening of the limb and by retarding or completely arresting the bony growth.

After a final inspection of the whole field of operation the wound is syringed out with formalin solution and deposits of plugging material are introduced and protected with oiled silk, the tourniquet is released and the bleeding is arrested by ligation. The halves of the patella, having been denuded of their cartilaginous surfaces by the saw, are brought into apposition by a catgut suture which unites the para-capsular soft parts; the wound is drained through the angles. Before the insertion of this suture the plugging material is poured into the gap between the tibia and the femur. The cavity resulting from the extirpation of the supra-patellar bursa is rubbed over with some iodoform powder and the drains are inserted into it. Sutures, or Michel's clamps, complete the operation. The preservation of the dorsal halves of the patella primarily fulfils a cosmetic purpose, in that it prevents the otherwise characteristic indrawing; but it also serves as a buttress of bone which lies perpendicular to the resected joint surface, and acts to a limited degree as a check against a later genu recurvatum and secondary contraction. The patella should only be completely excised if it is quite carious.

Formerly silver wire was used to unite the segments of the patella; then a thread of catgut was wound around them. Now sutures are passed through the thin prepatellar layers—viz., the aponeurotic expansion of the quadriceps tendon and the periosteum. This suffices as the bony segments are subject to no tension. Pegging of the resected articular ends has never been resorted to; it is quite unnecessary if the saw is used sparingly or a cartilage knife is exclusively employed for the resection. The securing of the ends of the resected joint is effected by a splint. This consists of a hollow trough of wood or celluloid rendered aseptic, and of such a length that it extends from beyond the middle of the posterior surface of the thigh on the one hand to the middle of the calf on the other. The trough is padded with the requisite amount of sterile cotton and gauze and applied to the under surface of the limb as soon as this is ready for dressing. By padding the splint accordingly complete extension or any desired angular position of the ends can be obtained. The leg is then secured to the splint with sterile gauze rolls. This constitutes the "inner dressing." Finally, the whole extremity, from the hip to the toes, is wrapped in a large sterile quilt of wood wool and the "outer dressing," consisting of starched bandages and strips of wood, is fixed in position over it.

If the progress of the wound is aseptic the first dressing commonly remains *in situ* three weeks. The change is readily and painlessly effected by cutting the outer bandage with a small knife and turning it back. The gauze rolls are then snipped through with a pair of scissors and the resected region is laid bare. The drains and sutures may now be removed. Then a fresh splint, padded and ready, is promptly substituted as the old one is removed. The patient scarcely notices the exchange of splints when it is conducted properly, even if the dressing requires to be changed before the third week.

Hip-joint.—The joint is exposed from the posterior side by means of Textor's incision, the capsule opened, and the head dislocated and sawn off through the neck. The healthy acetabulum is then filled with plugging material. The case pursues a perfectly aseptic course. All personal experience[4] is lacking in cases of coxitis tuberculosa, as material of this nature is not obtainable. No doubt, however, can be entertained that the plugging will prove of service in these cases.

The face.—Lately the application of iodoform bone-plugging has been extended to the filling of bone cavities in the facial skeleton—certainly the first cases to receive this kind of treatment. They comprise four cases of dental cyst and two of empyema of the antrum of Highmore. In two instances the dental cysts were situated in the superior maxilla. The first case of dental cyst was explored from the exterior after splitting the cheek by Langenbeck's semi-lunar incision, as the diagnosis appeared uncertain, and the possibility of its being a sarcoma could not be excluded. The exposed anterior wall of the antrum was removed above the reflection of the buccal mucous membrane without opening into the mouth and the cyst wall was carefully extirpated. After the cavity had been well dried it was filled up with "bone plugging" and the wound in the cheek was sutured. Perfect healing by primary intention resulted. A dental cyst in the mandible was also explored from the exterior by division of the soft parts on to the body of the bone. After elevation of the periosteum an incision was made through the thinned external wall of the cavity, which corresponded in size to a goose's egg. In the interior of this the naked roots of the last molar tooth, which was somewhat dislocated in its socket, were found to be projecting. The tooth had to be extracted, whereby the former exclusion of the cyst cavity from the interior of the mouth was lost and an open communication established in the alveolus. After extirpation of the cyst wall and drying the cavity the communicating canal was temporarily stopped with a finger and the cavity filled. As soon as the plugging material had set the external wound was closed with sutures. Healing by primary intention followed. When the patient's mouth was open the bulging inner wall of the former cyst could be discerned and on the apex of this was situated an aperture of about the size of a hemp seed through which the stiff yellow "plugging" protruded. By degrees the internal prominence of the mandible subsided, and the patient left the ward four weeks later devoid of symptoms and with a normally shaped lower jaw.

After the experience gained from this case—viz., that a communication between a plugged cavity in the maxilla and the mouth did not militate in any way against the final success of the operation—a second case of cyst in the lower jaw was operated upon. This was of about the size of a large plum and extended from the lateral incisor to the second bicuspid. The cyst was exposed, not from the exterior but by retracting the lower lip from the gum. A transverse incision was first made into the gum, corresponding in length to the tumour and near to the reflection of the mucous membrane on to the lower lip; the gum, together with the periosteum, was next elevated from the thin papery outer wall of the cyst, the latter was incised, and the greater part of it was removed. Extirpation of the thickened cystic membrane proved very difficult owing to the existence of diverticula between the bare roots of the teeth and the task of separating these from the whole row of loose teeth, extending from the lateral incisor to the first molar occupied a considerable time. By the intelligent coöperation of the patient, who had not been anæsthetised, in adjusting the position of her head and body, perfect success attended the introduction of the filling substance. After the plugging had set the wound in the gum was sewn up with fine catgut. Apart from a slight swelling of the same side of the face no symptoms were noticed. The case followed an afebrile course and closure of the wound was successful. On the third day the patient left the ward. 14 days later she presented herself in the out-patient department; no swelling was visible and the teeth were set decidedly firmer. She expressed herself highly contented with the operation.

---

[4] Of Professor Moorhof.

The second case of empyema of the antrum was also dealt with from the mouth, without general narcosis and with the aid of some cocaine and adrenalin. The second molar tooth was lacking; through a defect in the alveolar process the sound could be passed into the maxillary sinus, causing some discharge of pus. On irrigation none of the syringing solution escaped from the nostril. The gum was incised transversely, somewhat below the line of reflection of the mucous membrane, the parts along the canine fossa were raised, and a portion of the anterior bony wall of the sinus, [illegible] gth and breadth to a ter- [illegible], was removed. To effect [illegible] employed to make a breach in the wall and the resulting aperture was subsequently enlarged by means of bone forceps. The investing mucous membrane was now extirpated with the aid of a forehead mirror. On the completion of this troublesome step and it being ascertained by means of the eye and finger that bare bone alone was present, the cavity was filled by tilting the patient's head into a suitable position. Catgut sutures, closely inserted, were employed to unite the gum as soon as consolidation had taken place. Before the introduction of the plugging a small strip of iodoform gauze was inserted into the socket of the tooth and this was subsequently left *in situ*. The course was afebrile and there was slight swelling of the affected side of the face which lasted three days. The patient was discharged on the fourth day. On examination with the Roentgen rays a deep shadow was manifest throughout the whole extent of the antral cavity. The lightly inserted strip of gauze which served as a temporary plug for the socket of the tooth was withdrawn on the third day and the filling substance henceforward remained, not only in communication with the mouth but also with the nasal fossa. In spite of this, however, the material remained intact and performed its function as a "locum-tenens" without producing any disturbance. When one considers how difficult [illegible]

Cysts of the maxillæ are bone cavities arising in consequence of pathological changes; there appears, however, to be no doubt that such spaces may become completely obliterated by the gradual approximation of the expanded, shell-like, bony walls. It is another question with an empyema of [illegible] bliterated in the same way, [illegible] l pre existing cavity the [illegible] s become diseased through inflammation? Perhaps in a year the question may be settled. For the present it is sufficient for the patient in so far that he can be relieved of his troublesome symptoms in a few days [illegible] nd the complicated [illegible] ntinuing for years, [illegible] is, and remains, [illegible] no disagreeable odour is communicated to the expired air.[3]

The mediastinum.—Before concluding mention must be made of a case in which, willy nilly, Professor Moorhof had to resort to plugging and it is adduced as evidence of the extraordinary toleration of the plugging material by the organism in general. It concerns the plugging of a mediastinum. A 14-year-old girl was recommended to Professor Moorhof from a college in Bohemia. On examination she presented nearly in the middle of the sternum a crateriform ulcer of a tuberculous nature which secreted an abundant discharge; a second ulcerating sinus opening of a similar character was located in the suprasternal fossa immediately above the manubrium sterni. Both led down into the mediastinum. It was decided to operate on this case in spite of the existence of intercurrent bilateral affection of the apices, because evening fever was present and the complete loss of appetite and the copious secretion were undermining her strength. At the outset certainly the case was not deemed to be so difficult as it eventually proved. It was hoped that the disease had originated in the bony skeleton—namely, the sternum—inasmuch as a scar was present on the fourth right rib, which imparted the information that at some time previously the rib itself had been scraped out, [illegible] tending from [illegible] ings of the si [illegible] o the anterior mediastinum was obtained by this means. The whole mediastinal cavity was found to be filled with broken-down caseous masses which had displaced the right pleura and pericardium and penetrated to a "frightful depth." The débris was first carefully removed with an ordinary blunt spoon and a deep cavity larger than a man's fist was thereby excavated. The heart and pericardium were thrust to the left; on the right side the pleura stretched back to the root of the lung, on which a large vessel, possibly the superior vena cava, could be seen pulsating. But this was not all; above and below the root of the lung a fistula was found which delved into the posterior mediastinum. After the removal of the caseous masses both diverticula happily proved to be blind. The pleura and pericardium were manifestly thickened and covered with a friable grey pyogenic membrane. No further doubt remained, however, judging from the appalling conditions present, that the mediastinal complications arose, not from the thoracic skeleton but from broken-down tuberculous bronchial glands. With the aid of a sharp spoon the membrane was cautiously peeled off and on the completion of this a very large and extremely dilated cavity stood revealed the right wall of which was formed by the thickened and rigid pleura, the left by the displaced pericardium; below its lower wall was constituted by the diaphragm and towards the neck it was limited by the lower border of the thyroid gland. What was to be done? There was the copious secretion from the imperfectly removed pyogenic membrane to be apprehended and still more the inevitable decomposition of the wound secretion in the secondary recesses around the root of the lung, hence sepsis and erosion of the vessels. In this predicament the entire cavity was filled with plugging, confiding in the well-tried properties of iodoform. So large was the cavity, however, that more than 200 grammes of the material were utilised and still an interval nearly one centimetre in depth to the level of the sternum remained to be filled.

The result was astonishing. The evening fever ceased, the appetite returned, the nights were good, and the patient quitted her bed on the seventh day and went into the garden. After the dressing was changed on the second day the secretion from the wound became moderate and merely necessitated a fresh dressing every fourth day. The plugging was slowly eliminated and whilst immediately after the operation it did not reach the level of the skin, on the eighth day it protruded through it and was superficially exposed. In 14 days the patient felt quite well and wished to return home, so she left the sanatorium and returned to Bohemia in charge of her mother. The local practitioner had the kindness to keep Professor Moorhof posted concerning the progress of the patient. Some days after their arrival home, on May [illegible] been performed on [illegible] which suddenly deve [illegible] ck of asphyxia. The latter, after lasting about a quarter of an hour, ceased with complete restoration to the normal condition. [illegible] ing day. [illegible] and this [illegible] patient to enjoy a quiet night with undisturbed sleep. Nevertheless, it reappeared during the next forenoon and subsequently the attacks recurred two or three times daily with truly disquieting symptoms. Narcotics procured no relief. Hitherto the dressings had been changed only every four days; now, however, as a mucous discharge was also [illegible] escaped during respiration through the lower wound with an audible sound. No portions of the plugging material had

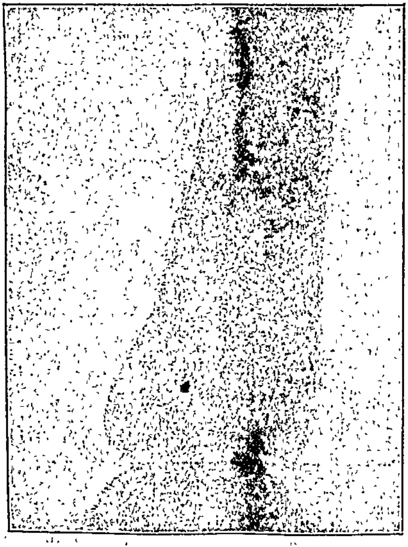
been coughed up at this time. The sputum was only moderate in quantity and consisted of tenacious transparent mucus. The pulse was accelerated (up to 160). No fever was present. On the morning of June 5th an attack again supervened, during which the face became œdematous and markedly cyanotic. The girl succumbed on June 7th to the progressive increase of these symptoms. The plugging also in this instance acted as a "locum-tenens," but that it could effect a cure in such a hopeless case no one for an instant ventured to believe. Enough that it was tolerated and that sepsis was prevented.

Appended to the above in the original monograph is a compilation of the histories of all the cases operated upon by Professor von Mosetig Moorhof. The collection comprises some 79 cases of osteomyelitis, 108 cases of tuberculous disease, two orthopædic cases, two fillings of the antrum of Highmore, and four of dental cysts. Professor Moorhof states, in conclusion, that in no single instance has he to report a failure. From this appendix one case has been selected which has immediate reference to the illustrative reproductions of skiagrams. (Figs. 1, 2, 3, 4, and 5.)

FIG. 5.



Thirty-three weeks after operation.

The patient was a stonemason, aged 28 years. In July, 1902, he had an abscess on the lower part of the right leg which was incised. At the end of October a fistula formed with copious secretion. When seen on Nov. 22nd the region over the internal malleolus was swollen; a sinus was present leading down to raw bone. A diagnosis of osteomyelitis tibiæ was made. On Dec. 5th erasion was performed with subsequent plugging of a cavity in the tibia of the size of a hen's egg. On Dec. 14th the dressings were changed. The wound healed by first intention. The patient was discharged healed on March 11th, 1903.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At a stated meeting of the Royal College of Physicians of Ireland held on Jan. 13th the following candidates were admitted to the Membership of the College: Edward J. M. Watson, M.D. Dub., and T. Gillman Moorhead, M.D. Dub. At the previous meeting of the College held on Jan. 6th Lieutenant-Colonel F. O. Reeves, I.M.S., was admitted to the Membership.

A CASE OF ACUTE LEUKÆMIA,

WITH REMARKS ON ITS CLINICAL FEATURES AND DIAGNOSIS.

BY W. MITCHELL STEVENS, M.D. LOND., M.R.C.P. LOND.,
FELLOW OF UNIVERSITY COLLEGE, LONDON; ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE CARDIFF INFIRMARY.

CASES of acute leukæmia which are usually of the lymphatic type are especially prone to occur in young subjects and they are of much clinical interest as the difficulties in diagnosis may be very great. The case which I am about to record occurred some months ago in the practice of my friend, Mr. F. Temple Morris, to whose kindness I am indebted for seeing it.

The patient, a boy, aged 17 years, complained of general weakness, slight headache, loss of appetite, and painful priapism. The family history was good. The lad himself had enjoyed excellent health until his present illness which commenced one week before sending for his medical attendant with the above-mentioned symptoms. Six months previously the patient had fractured his thigh but he had rapidly recovered from this accident. When first seen on the eighth day of his illness he showed marked pallor and weakness; the temperature was 102° F., the pulse was 84, and the respirations were 24, and a careful physical examination failed to discover anything except very marked and continuous priapism. On the tenth day of illness the blood was tested for Widal's reaction with a negative result. On the thirteenth day of illness I saw the patient in consultation with Mr. Temple Morris and his condition was as follows. He was dull, apathetic, and irritable and complained of headache, weakness, loss of appetite, and great pain in the penis, with difficulty in passing his urine. He was pale, prostrated, and wasted. His temperature was continuously raised and varied irregularly between 100° and 103°, the pulse was 98 and regular though weak, and the respirations were 26 The skin was dry and sweatings were absent and a careful inspection showed a few small hæmorrhagic spots on both flanks. There was no glandular enlargement. The appetite was very poor but there were no gastro-intestinal symptoms and the bowels were regular and the stools were normal. The tongue was clean though dry, the gums were normal, there was no abdominal distension or tenderness, the liver was not palpable, but the spleen was slightly enlarged but not tender. The heart and lungs were normal, as was the urine. The penis showed marked priapism which condition was continuous and painful. A blood examination showed red corpuscles 1,620,000 per cubic millimetre and leucocytes 920,000 per cubic millimetre and it was found that the excess of leucocytes was due entirely to the large lymphocytes. On the twelfth day it was found that the spleen was still further increased in size and distinct enlargement of the glands in both axillæ and in both groins was felt. The patient sank rapidly and died 19 days from the commencement of the illness.

The following points are, I think, worthy of note: 1. The duration of the illness. The entire illness lasted less than three weeks. 2. The general symptoms. The mode of onset and the general symptoms (headache, malaise, pallor, and continued fever) suggested the probability of typhoid fever and the possibility of tuberculosis or of malignant endocarditis or some "septicæmic" condition. Typhoid fever, however, was excluded by the absence of any other symptoms or signs of the disease, including Widal's reaction, and, moreover, the course of the pyrexia and the presence of priapism militated against that disease. Tuberculosis and malignant endocarditis were excluded by the history and by a thorough examination. 3. Splenic enlargement. This was not noticed until the thirteenth day of the illness. The spleen was only slightly enlarged and it was very firm and not tender. The splenic enlargement, associated with pallor and with purpuric spots on the flanks, suggested some diseased blood condition. It is to be remembered, however, that in cases of lymphatic leukæmia the spleen is not always obviously enlarged. 4. Glandular enlargement. Enlargement of the lymphatic glands did not make its appearance until after the thirteenth day, by which time the diagnosis had been made by means of a blood examination. It may be noted that the glandular enlargement progressed rapidly in the last few days of life. 5. Blood examination. This showed conclusively that the case was one of acute lymphatic leukæmia. An interesting point in this connexion is the enormous number of lymphocytes present. 6. Priapism. During the whole of the time that this patient was under observation there was marked and continuous priapism and this condition gave rise to much distress. In conclusion, one may say that a case like this shows the very great clinical importance of a blood examination in doubtful cases and, indeed, in this instance it was thus possible to diagnose the presence of lymphatic leukæmia before any glandular enlargement was observable.

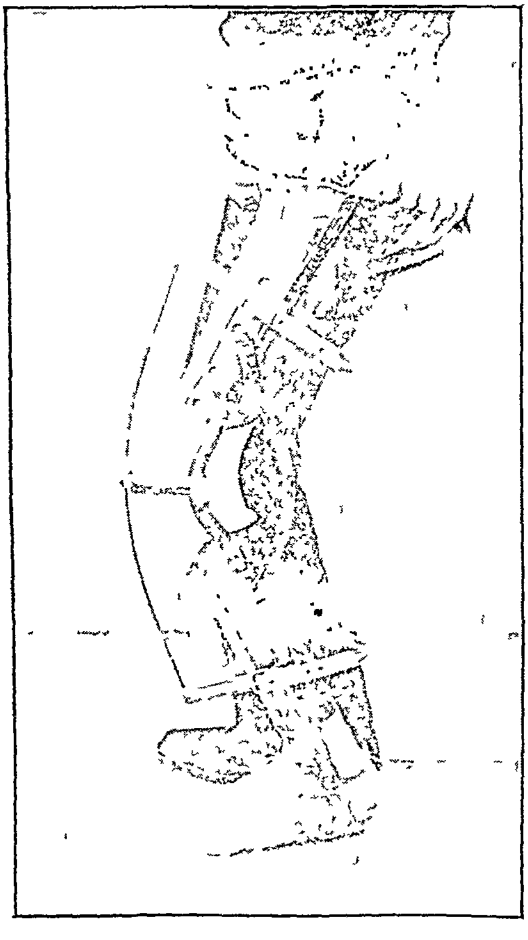
Cardiff.

A CASE OF CONTRACTURE AND ANKYLOSIS AT THE KNEE TREATED BY STEEL-BAR TRACTION AND HESSING'S SPLINT CASE APPLIANCE.

BY T. H. OPENSHAW, C.M.G., M.S. DURH., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL AND SURGEON TO THE NATIONAL ORTHOPÆDIC HOSPITAL

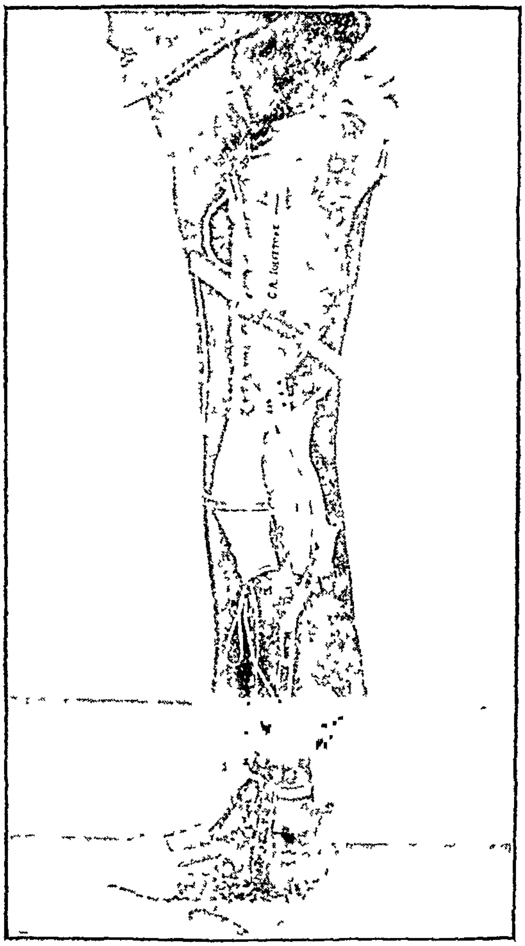
THE patient, a boy, aged 15 years, came under my care at the London Hospital in January, 1904, with close fibrous ankylosis and contracture of the left knee. The knee first became painful and stiff when the patient was five years old. He was treated with plaster of Paris, &c., but abscesses formed which burst. There were two cicatrices above the external condyle and one over the ligamentum patellæ and evidences of extensive tuberculous disease resulting in ankylosis. The knee became flexed and contracted and this remained so, but during the year 1903 it had been getting slowly more marked. In January, 1904, the angle of the knee-joint was 112 degrees. The hamstring muscles were contracted. There was power of motion of the knee only to the extent of one degree. The muscles of the thigh were wasted but there was no paralysis. The patient walked well with the toes on the ground but the left half of the pelvis dropped four inches in order that the toes should reach the ground. There was marked left dorso-lumbar lateral curvature.

FIG. 1.



The apparatus applied, Feb. 26th. The knee is flexed at an angle of 112 degrees.

FIG. 2.

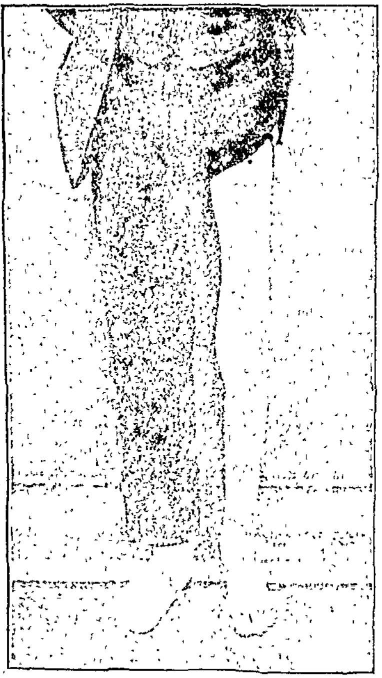


Showing the knee straight on April 15th.

On Feb. 26th Hessing's splint case appliance, with steel-bar traction, was adjusted to the limb, the knee being then flexed at an angle of 112 degrees (see Fig. 1). Very slowly and steadily the knee began to extend, without pain, œdema, or other inflammatory symptom. As the knee extended so the arched steel bar at the back of the knee was readjusted and on April 15th the leg was straight (see Figs. 2 and 3). The accompanying diagram (Fig. 4) shows the steady improvement that had taken place at different dates.

The appliance consists of three cases made of leather, one accurately moulded to the thigh, a second to the calf, and a third to the foot. Each is strengthened with steel bars. These steel bars are accurately moulded to the part and are then sunk into the softened leather. These bars carry certain plates of steel which project through the leather and in which are various screw-holes for their firm attachment to two lateral steel bars which pass down from the thigh case to the ankle. The leather cases by this means not only are firmly attached to the lateral bars but can be adjusted either a little upwards or a little downwards. The splint thus forms one uniform whole which accurately fits

FIG. 3.



Front view of straight leg, April 15th.

the leg from the ankle-joint to the top of the thigh. Each leather case is open in front and is made to lace up.

The foot leather case is fitted with a sole plate carrying upright bars on each side with steel pegs in them. The pegs fit in holes at the lower end of each of the lateral bars and by this means traction upon the lower part of the leg is made. Crossing the front of the knee is a steel arch fitted on each side into the joint between the thigh and the leg. It carries a slot through which passes an elastic steel bar, to each end of which is attached a strap. These straps buckle to the lateral steels of the thigh and leg cases (see Fig. 1). The upper end of the steel bar having been buckled tight, as the lower straps are tightened so the leg is drawn forward and the knee is straightened. At the back of the knee is an arched steel bar, with a slot at the lower end and with screw-holes at the upper end. As the leg gets straighter the straightening is followed up and secured by increasing the length of this bar. The slot at the lower end of the bar allows the knee to extend but prevents flexion.

Remarks.—This case was one of the closest possible fibrous ankylosis, practically no movement being obtainable at the knee-joint. The contracture and flexion of this joint were steadily getting worse, so that only the tips of the toes touched the ground, and the pelvis being tilted scoliosis resulted. The knee was straightened in six weeks without any pain being experienced during the process. The patient was *not incapacitated even for a day.* The *movement* at the knee-joint continued very slowly to increase in extent.

In my opinion, every case of fibrous ankylosis and contracture of the knee can be straightened by means of this steel-bar traction method. This method should supersede forcible straightening of the knee under anæsthetics, which occasionally results in rupture of the popliteal vessels or in lighting up the quiescent tuberculous disease and frequently causes an increase of the pre-existing stiffness of the joint.

HUMAN PIROPLASMOSIS.[1]

BY C. DONOVAN, M.D. R.U.I.,

MAJOR, I.M.S.; SECOND PHYSICIAN, GENERAL HOSPITAL, MADRAS.

(Concluding Part.)

THE piroplasmata are found in the peripheral circulation, the spleen, the liver, the bone marrow, the submucosa of the large intestine, ulcers of the skin and large intestines, and occasionally in the kidneys and the suprarenals.

In the peripheral circulation the parasite is met with in the red blood corpuscles and in the polymorphonuclear and mononuclear leucocytes; it is only when the temperature is high, between 103° and 104° F., that their occurrence in this situation is noticed. Their numbers vary and are never at any time great; in an examination of a slide for half an hour six might be found in the red blood corpuscles and double to treble that number in the leucocytes. In the red blood corpuscles the organism is small, 1 μ to $1\frac{1}{2}$ μ in diameter, in shape bacillary, pear-shaped, oval or spherical, with one *chromatin* mass, oval or oblong, always placed at the circumference. The forms represented in Fig. 7 of the coloured plate attached [illegible] their different shap[illegible]g the one-chromatin parasite are not altered in shape, size, or in staining reaction from the normal uninfected cells. Here also may be found rarely shrunken red cells stained blue instead of *greenish-yellow, which contain* the double chromatin parasite to be described immediately below. In [illegible] leucocytes (Fig. 7) [illegible] ing life the forms are varied and numerous, they occur free, in altered and unaltered red blood corpuscles, in the protoplasm of the mononuclear leucocytes and macrophages. The most typical form is either oval or spherical, measuring 2·5 μ to 4 μ by 1·5 μ, with two chromatin masses, staining deeply with methylene-azure, especially the smaller of the two which takes on a clearer and more brilliant shade of the stain; the two chromatin masses are placed opposite each other, the larger, round or oval, has, as a rule, a looser texture than the smaller one which is more compact and dot or rod shaped (*vide* Fig. 1). With deeper Romanowsky staining a chromatin thread appears to connect the smaller mass to the periphery of the organism (*vide* Fig. 2) and at times a similar thread connects the two masses. In some preparations vacuoles appear to exist in the cell body but these I consider artificial (*vide* Fig. 2). The cell substance of the parasite is very clear and hyaline and not granular; it usually stains a light greyish pink with Romanowsky stain, the shade being darker at the periphery than towards the centre. However, if the preparation is well and carefully cleared with alcohol the protoplasm comes out a light blue, darker at the periphery with strands extending towards the larger chromatin mass. Such an appearance is shown in Fig. 3. Besides the above described there are pear-shaped and fusiform forms possessing one or two chromatin masses and stages in the multiplication of the parasite by bipartition and multipartition (*vide* Figs. 1 and 5). A few of the organisms possess a very light-coloured larger chromatin mass with an accentuated dark smaller one; two are shown in Fig. 1.

---

DESCRIPTION OF PLATE.

(Magnification about 1500 diameters; Romanowsky staining was used.)

[illegible] forms of piroplasma Donovani found in blood [illegible] s and [illegible] asite. [illegible] t in red blood corpuscles [illegible] ion.

FIG. 8.—Macrophage from spleen blood with numerous piroplasmata in protoplasm, one apparently in the nucleus. Nucleus of splenic cell with dark nodal *staining resembling piroplasma* Donovani in appearance.

FIG. 9.—Blood taken from a smear post mortem.

The piroplasma when included in the red blood corpuscles brings about marked changes in the structure and staining properties of the stroma; as long as the parasite possesses a single chromatin mass the red cell is unchanged but on the advent of the smaller chromatin mass the infected cell alters in its staining reaction. The normal yellowish-green colour of the cell assumes a blue tinge, beginning at the periphery and extending towards the centre till the whole infected cell is changed from a homogeneous yellowish-green disc to a finely reticular and blue-stained form (*vide* Fig. 4).

The altered red blood corpuscles at times increase in size when harbouring more than four or five parasites and at times decrease when containing a single individual. Appearances of double chromatin parasites included in unaltered red blood corpuscles I consider delusive; the organisms in such cases are superimposed. (But this statement I make with great reserve as those skilled and experienced observers, MM. Laveran and Mesnil, consider them as inclusions.)

The number of organisms in the mononuclear leucocytes vary from two or three to half a dozen, but it is in the macrophages that we meet with them in large quantities, where from 150 to 200 may be counted, crowded and packed in the protoplasm of one of these giant cells (*vide* Fig. 8). A few may be seen in the nucleus but these are probably superimposed. As a rule pigment is not associated with this piroplasma but in about seven of the cases there was well-marked evidence of such an occurrence. The pigment was of golden-brown to vandyke-brown in colour, present both in the altered red blood corpuscles and the protoplasms of the mononuclear leucocytes and macrophages (*vide* Fig. 6). The pigment was not an artefact; special care was taken to exclude such an accident. In the above cases pigmentation was present in the liver and spleen examined macroscopically and microscopically. In the smears taken from the spleen post mortem the organism is not so well defined as during life; it is smaller and the outline of the cell of the parasite is by no means so well demarcated. The two chromatin masses in juxtaposition, however, draw one's attention to their presence in the preparation (*vide* Fig. 9). The likeness of the parasites to changes in the nodal thickening in the nucleus of the splenic pulp cells is marked and would give rise to confusion to an inexperienced observer. (*Vide* the nucleus of the splenic cell in the sinus below the long horizontally extended pseudopodium of the macrophage in Fig. 8, where this deceptive appearance is shown). I have not touched on the microscopical appearance of the tissues and organs found in this disease as leisure was denied me in entering into but a cursory examination of such preparations.

As to the nature of the parasite, I consider myself justified in adhering to the experienced and authoritative opinions of MM. Laveran and Mesnil. The one chromatin forms in the peripheral circulation have the closest resemblance to piroplasma bigeminum but I have not so far succeeded in observing any enlarged spleens in calves suffering from "Texas fever" in Madras so cannot compare the full-grown double chromatin forms (probably gametes) of these species of piroplasma. I may say, however, that I exclude entirely the genus trypanosoma as having any relation to the disease. I have now examined carefully fully over 1500 slides of blood of patients suffering from piroplasmosis and have never come across anything having the least resemblance to a trypanosome. Yet I do not exclude a trypanosoma, or rather a trypanosomoid stage, in the life-cycle of piroplasma infection.[2]

SUPPURATIVE PERICARDITIS.

BY R. W. MURRAY, F.R.C.S. ENG.,

SURGEON TO THE DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

THOUGH many cases of suppurative pericarditis have been recorded in which recovery has taken place still the mortality of this disease must remain very high. It is chiefly by surgical means that relief or a cure can be hoped for, and with the view of encouraging the early employment of free drainage of the pericardial sac I give an account of an illustrative case.

The patient, a boy, 13 years of age, was admitted into the David Lewis Northern Hospital on August 9th, 1904. He had enjoyed good health until a week previous to his admission, when his right ankle became swollen and painful without apparent cause. A few days later there was a painful swelling of the left great toe. Both ankle and toe had been poulticed. On admission the boy was very ill and complained greatly of his ankle, which was red, swollen, and acutely tender. The great toe was in the same condition. His respiration was so rapid that he spoke with difficulty, his temperature was 100° F., and his pulse-rate was 140.

It was obvious that the boy was suffering from suppurative arthritis involving the ankle-joint and also the metatarso-phalangeal joint of the toe. Chloroform was administered, the ankle-joint was rapidly and freely opened, and a drainage-tube was passed through it. The cause of the suppuration was found to be due to acute osteomyelitis of the lower end of the tibia. The great toe joint was at the same time dealt with and a similar condition was found there. In accordance with a practice which I have for a number of years invariably adopted in cases of this nature I examined the pericardial region The heart sounds were faintly audible and the pericardial dulness or rather flatness was markedly increased upwards and also extended to the right of the sternum I strongly suspected that this was *due to an accumulation of pus and the diagnosis being con*firmed by means of an exploring syringe I at once opened the pericardium by making an incision in the fourth left intercostal space, three quarters of an inch from the margin of the sternum With dressing forceps the incision was enlarged and a quantity of greenish yellow pus escaped A drainage tube was inserted At the completion of these operations, which were all done at one time the boy s condition was extremely grave He rallied however, in the course of a few hours and after a prolonged convalescence made a very satisfactory recovery

---

[2] Vide Schaudinn's wonderful preliminary contribution, "Generations und Wirtswechsel bei Trypanosoma und Spirochaete" in the Arbeiten aus dem Kaiserlichen Gesundheitsamte, Band xx., Heft 3, pp. 387 and 438, 439.

In the after treatment of the case the chief difficulty we had was in connexion with the imperfect drainage of the pericardial sac The incision made for this purpose was directly over the heart, with which the drainage tube came in contact, and I firmly believe the boy s ultimate recovery was largely due to the care and attention bestowed upon him by my house surgeon, Mr F St John Barry, who twice daily for several weeks passed a catheter through the wound and round to the back of the heart and then by means of a small glass syringe attached to the catheter washed out the pericardial cavity The wounds of the ankle and toe healed long before the pericardial wound which finally closed on Nov 1st having discharged for nearly three months The boy left the hospital on Nov 10th and apart from a little lameness is in excellent health

Though I have several times operated for suppurative pericarditis this is my one successful case I would draw attention to what I believe to be an important clinical fact—namely, the not infrequent association of suppurative pericarditis with acute osteomyelitis Why in such cases the pericardium should become involved I do not know but I have so frequently met with this complication that I now invariably examine for it and the sign I place most reliance upon is increased cardiac dulness Another point of interest is how best to drain the pericardial cavity, for in this class of case if there is increased pericardial effusion it is almost certainly purulent and, if circumstances permit of it should be evacuated

A number of different methods of operating have from time to time been suggested many of them too elaborate and extensive to be of any practical value for in dealing with a case of suppurative pericarditis one is dealing with an acute abscess in a very ill person and whatever is done in the way of an operation must be done quickly As the opening must be made from the front it is impossible to obtain dependent drainage so long as the patient lies on the back, but if the opening is made in the costo xiphoid space as suggested by the late Mr Herbert W Allingham, together with removal of a portion of the seventh costal cartilage if considered necessary, as recommended by Mr Herbert S Pendlebury, then with the patient propped up in bed we have the most dependent oper
obtained If for any reason
satisfactorily maintained, I wo
gentle irrigation as was so successfully done in the case to which I have referred

Liverpool

CONGENITAL MULTILOCULAR CYST OF THE OMENTUM

BY W McGREGOR YOUNG, M A, M D GLASG

IT but rarely happens that amongst the enormous amount of medical literature published at home and abroad the searcher has any difficulty in finding reports on cases similar to his own But the condition in question must be a rare one for after a most diligent seeking in all the sources available to me I have found but one other case of the above disease That one was reported by Professor Hearn of Philadelphia in the Annals of Surgery for 1897 and in describing it the author makes the remark that he has found no note of any similar case On this account alone I think the following details are worth recording at length but the unexpectedly successful termination of the case has, I confess given me a stronger reason for making a report

The patient, a girl aged nine and a half years although looking younger, was brought to see me on account of a swelling in her body She was a child with a sallow, rather pasty complexion and small for her years Her mother had noticed the body decidedly swollen and large for more than *a year previously and had taken her about* that time to see a medical man who pronounced it ' consumption of the bowels ' The mother thought the child was always full and prominent in the body from infancy No pain was complained of nor apparently discomfort, child like she accommodated herself to her condition She was easily tired and readily out of breath although she could sleep without propping up She was much emaciated in the chest the arms, and the legs She had attended school up to three months previously and even now ran about and played Appetite and digestion were good and the bowels were regular On examination the body was seen to be enormously distended and nearly uniformly so but probably more in the epigastric region Distended veins were marked on its surface, the lower ribs were bulged outwards The body was firm and elastic, there was no hardness or rigidity anywhere There was complete dulness to percussion all over—not a resonant note anywhere Turning her on either side made no difference nor in the erect position was there anything but a dull note in the epigastrium Fluctuation was evident and a very decided thrill wave made it certain that it was fluid I was puzzled how to reconcile these facts but decided that the peritoneal cavity was so completely full as to explain them—an erroneous conclusion As the child s breathing was becoming more embarrassed an operation was advised I could think of nothing more likely than tuberculous peritonitis and so informed the mother that draining away the fluid might probably cure and would certainly relieve the condition The temperature was normal and the urine contained no albumin The lungs were crowded up and the heart was displaced upwards and outwards beyond the nipple line

A small incision being made in the middle line and the peritoneum opened a bit of what appeared like gangrenous bowel protruded through but no fluid came Prolonging the incision upwards to the umbilicus and downwards to near the pubes I made clear by putting in my fingers that I had a cystic condition to deal with and evidently multilocular I tried tapping but the cyst wall was so thin and offered so little resistance that there was no success I therefore incised and a gush of dark brown fluid evidently broken down blood and serum followed As this emptied but one loculus I required to treat the others within reach in the same way After relieving the cavity of a large quantity of fluid I could insert my whole hand and feel the extent of the tumour I found that it extended to the stomach beginning near the pylorus and reaching round the great curvature to the cardiac end and from there right across to the spleen the gastro splenic omentum consisting of one large loculus The child became very ill under the ether and as the anaesthetist (Dr S Clark) gave a very bad account of the pulse and the task of removing the whole was a very formidable one I thought it better to tie off what there was of collapsed cyst wall about two inches above the level of the umbilicus This I did in the usual way as if dealing with normal omentum, for omentum it clearly was and in fact by dragging upwards the wound Mr J J Anning who assisted me, and I had a good view of the stomach with the dark purple cysts bordering and overlapping it intimately around A good deal of mopping out was required to be done in the pelvis where the organs were *quite normal In making the toilet* of the cavity before closing I found a bit of healthy omentum running up to the transverse colon so that evidently the cysts involved only the anterior layers of the great omentum The fluid that was caught measured 32 pints but five or six pints more at least must have run to the floor, much to our discomfort The fluid and cyst wall were unfortunately not examined

The little patient was much collapsed after the operation but soon rallied with the help of strychnine and saline injections and three or four hours later was quite bright and cheerful She complained so much of thirst that I allowed her then half a pint of weak tea and milk During the first seven days she did well, the pulse was good the temperature was normal and nutriment was taken fairly Some ounces of fluid were drawn off daily for the first few days and a lessening quantity during the next few days through the Bantock s tube left in to drain the pelvis A rubber tube was substituted for the glass one at the end of a week but this also was withdrawn by the tenth day. The temperature began to mount on the eighth day and remained continuously high for the next 18 days, between 101° and 103° F. During this time the dulness in the left hypochondrium and epigastrium increased in area, the cysts fringing the stomach, and specially that in the gastro-splenic omentum, were enlarging rapidly till they could be recognised as low as the left iliac region and thence in a diagonal line up to the pylorus. I thought the fever to be hæmorrhagic. The child took little support and became painfully emaciated; the abdomen was unevenly bulged. The rest of the story would be too long to repeat in detail here, but for the next six weeks the temperature ranged from nearly normal at some part of the day, usually morning, to 102° or more, usually at night, and then she began to recover. Her appetite returned, her colour improved, the pulse was less rapid, and by the end of June, three months after the operation, she was cheerful and comparatively well. The curious thing was that some time about the sixth week on percussing the abdomen I could find no trace of the cyst, there was resonance everywhere, and yet the body was much diminished in size. This shrinking of the abdomen became more and more marked until it was painfully retracted owing to the prominent bulging of the lower part of the chest wall. The remainder of the cyst had disappeared. It had apparently enlarged so rapidly as to burst itself and its fluid contents had been absorbed. Did this also account for the continuance of the high temperatures? At all events the child got well and after two months in a convalescent home she returned looking rosy, fat, and in good health and this in marked contrast to what her appearance had been from infancy—sallow, thin, and puny. She looks now (Jan. 15th) in the best of health and the abdomen is resonant everywhere. What marks the case as more certainly congenital was a fact elicited long after the operation. It seems that four and a half years previously while in the scarlet fever hospital the nurses were much astonished at the size of the child's abdomen and remarked upon it. Much credit is due to the care given to the case by the district nurse, to whom I am glad to make this acknowledgment.

Leeds.

FRACTURE OF THE ANTERIOR FOSSA OF THE SKULL DIVIDING THE OPTIC NERVE.

BY FRANK J. HATHAWAY, M.D. EDIN.,

ASSISTANT SURGEON TO THE WINDSOR AND ETON ROYAL INFIRMARY; LATE CLINICAL ASSISTANT TO THE WESTMINSTER OPHTHALMIC HOSPITAL.

THIS accident is sufficiently rare to warrant my publishing the following case which came under my care in the Windsor and Eton Royal Infirmary.

A man, aged 25 years, was cycling on May 20th, 1904, by night and collided with a tree. He lay on the ground unconscious for six hours and was then brought to the hospital. Here he was seen by the house surgeon and found to be conscious, with a severe contusion of the right side of the face and a wound over the bridge of the nose. There was much subconjunctival hæmorrhage in the right eye and both eyes were closed by the swelling of the lids. Three days after, when he was able to open his eyes, he complained that he could not see with his right eye. I was asked to see him and found the following condition. There was pain above the right eye and over its supra-orbital margin, which latter was tender. There was no ophthalmoplegia but a large amount of subconjunctival hæmorrhage was present. The right pupil was semi-dilated and not reacting to light but acting consensually. In the right eye there was absolutely no perception of light. The ophthalmoscope showed nothing abnormal; no changes in the vessels or other structures were to be seen. A diagnosis of division of the right optic nerve by a fracture of the anterior fossa was made and I watched him daily for signs of optic atrophy. On the seventh day it was noticed that there was some commencing pallor of the temporal side of the disc and on the fourteenth day that there was pallor of the whole disc, but especially on its temporal side. On the twenty-eighth day a note was made that the disc was quite white and in this condition it has remained. He is now absolutely blind in the right eye and the disc is very white. In the left eye vision and ophthalmoscopic appearance are normal.

The literature on this subject is very scant and I find very few recorded cases where a limited fracture of the anterior fossa has picked out and divided the optic nerve. Mr. H. B. Grimsdale tells me he has had one case under his care at St. George's Hospital and Dr. L. Phelps in his work on Head Injuries gives a list of six. Pathological examination divides these cases into two groups due to different causes—namely, (1) unilateral blindness following division of the optic nerve, and (2) that following hæmorrhage into the optic nerve sheath. Thus Professor Helferich in his work on "Fractures and Dislocations" states that of 168 cases of fracture of the skull eight cases of blindness were due to extravasation of blood into the optic nerve sheath. Mr. Jonathan Hutchinson notes that blindness of one or both eyes may follow a fractured base as a result of laceration of the optic nerve or of hæmorrhage into its sheath. Professor Tillmann in his "Text-book of Surgery" suggests that cases of blindness following fracture may be due to hæmorrhage or to direct injury of the optic nerve by a fracture passing through the optic foramen or indirectly by broken-off splinters of bone from the roof of the orbit or optic foramen. Mr. T. Pickering Pick said that if the fracture involves the lesser wing of the sphenoid laceration of the optic nerve may be produced. Mr. H. E. Juler in his work on "Ophthalmology" says that hæmorrhages into the optic nerve sheath are considered to take place but they have never been proved to exist. Professor Fuchs in his work makes no mention of hæmorrhages in the optic nerve sheath as a cause of unilateral blindness but (p. 493) says that in these cases of unilateral blindness following an indirect injury to the head we are dealing with fractures of the walls, particularly of the upper wall, of the orbit, which fractures are continued into the optic canal, so that the optic nerve in the latter is crushed or lacerated. Lately, Mr. L. B. Rawling, in his Hunterian lecture, 1904, has suggested that such damage of the optic nerve in fractures of the skull is caused by the anterior clinoid process being torn off and rotating inwards, so that the rough edge comes to press on and to lacerate the nerve. The balance of evidence in cases of unilateral blindness following an injury to the head is in favour of causation by a fracture of the anterior fossa which lacerates the nerve, and it seems improbable whether hæmorrhage into the nerve sheath has any effect in causing such blindness.

The escape of the ophthalmic artery from injury, which lying below and to the outer side of the nerve should in fracture through the optic foramen be damaged, seems to point to a splinter of bone, such as the anterior clinoid process, as the immediate factor in causing the division.

ST. MARYLEBONE INFIRMARY.

A CASE OF SUBCUTANEOUS EMPHYSEMA IN PULMONARY TUBERCULOSIS.[1]

(Under the care of Mr. JOHN R. LUNN.)

FOR the notes of the case we are indebted to Mr. D. Murray Ross, the assistant medical officer of the infirmary.

The patient was a man, aged 44 years, who was admitted into the St. Marylebone Infirmary on Nov. 17th, 1904, suffering from pulmonary tuberculosis of some months' duration. The physical signs denoted considerable infiltration and consolidation of the tissue of both lungs but no cavitation. Three weeks subsequently he complained of sudden pain over the region of the left apex. 12 hours later he complained of dyspnœa, pain in the neck and chest, swelling of the neck, and a sensation of suffocation. The anterior and lateral gested. The tissues crackled under the fingers and fine crepitations were heard over the affected parts on inspiration. The [illegible] the [illegible] side, [illegible] side. The lower limit was roughly the level of the third rib and the right limit an irregular line drawn from the right sterno-clavicular joint to the angle of the jaw on that side. The right posterior triangle was free, as was also the anterior surface of the chest on the right side. Examination at this time failed to show any signs of cavitation of the lung or of pneumothorax. The treatment consisted in the administration of morphine to quieten the breathing and absolute rest in bed with a low diet. For three days the limits of the crepitant tissue remained about the same but at the end of that time it was observed that the emphysema had completely disappeared, that the respirations had quietened, and that the neck had regained its normal proportions. Three weeks afterwards the man was in a state of health similar to that which he presented on admission, there being no return of the symptoms. It may be added that preceding the sudden pain he had made no violent respiratory effort nor did he become collapsed or cyanosed during or after the onset of the pain. No paracentesis of the chest had ever been performed on the patient.

Remarks by Mr. Ross.—Professor William Osler in his "System of Medicine" states that subcutaneous emphysema is a rare complication of pulmonary tuberculosis and gives as its probable cause either (1) perforation of the trachea or (2) rupture of a cavity. Abs [illegible] perforation of the trachea [illegible] particular case and the concl[illegible] cavity over which part of the left dome of the pleura was closely adherent had ruptured through its covering into the tissues of the neck. The further history of the case made it probable that the communication between the lung and the tissues became occluded by either inflammatory lymph or adhesions, with the subsequent absorption of the air in the subcutaneous tissues. In THE LANCET of Dec. 17th, 1904, p. 1714, Mr. R. D. Attwood records a case of subcutaneous or, as he calls it, surgical emphysema occurring as a complication of pulmonary tuberculosis. The present case appears to me, however, to be of even greater interest.

I am indebted to Mr. Lunn for permission to publish this case.

MANCHESTER CHILDREN'S HOSPITAL, PENDLEBURY.

A CASE OF ENCHONDROMA OF THE PATELLA.

(Under the care of Mr. J. H. Ray.)

For the notes of the case we are indebted to Dr. Charles Mackey, late senior resident medical officer.

The patient, who was a boy, aged nine years, was admitted to the Manchester Children's Hospital, Pendlebury, for swelling of, and pain in, the left knee. His family history had apparently no bearing on the case. The account of the illness which was given was to the effect that he had been kicked on the left knee some months previously and that [illegible] ee or four months— [illegible] ng on his left knee. [illegible]

On admission the patient was found to be a strong, healthy-looking, well-nourished boy. Examination of the left knee revealed signs of distension of the joint cavity with fluid—namely, slight flexion of the joint, contour of the swelling, fluctuation at the sides of the patella, and floating of the patella. There was a hard, non-fluctuant, nodular tumour arising from the outer and upper quadrant of the patella. This swelling was only moveable along with the patella.

Chloroform having been administered, Mr. Ray made a vertical median incision over the anterior aspect of the left knee. At the base of this wound bulging synovial membrane could be seen, which appeared to be enlarged lateral pouches extended in front of the patella, as on incising this the joint cavity was opened and much pale-yellow limpid fluid escaped. A nodular cartilaginous mass three and a half inches in diameter was seen arising from the upper, [illegible]. This was removed by bone [illegible] cavity was then irrigated with lotion of biniodide of mercury of strength 1 in 5000 and afterwards with normal saline solution. The wound was then closed with a single row of interrupted silk sutures and dressings were applied. The limb was fixed on a posterior splint with a rectangular foot-piece and also with an external lateral one. The patient left the hospital two months later with a firmly healed wound and a moveable joint. Seven months later he was reported to be quite well.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.

A CASE OF HYDATID DISEASE OF THE KIDNEY.

(Under the care of Dr. R. J. Paton.)

For the notes of the case we are indebted to Dr. W. D. Wright, late resident medical officer at the hospital.

A man, aged 50 years, was admitted into the Newport and Monmouthshire Hospital on June 6th, 1904, complaining of having been weak and out of sorts for the last 18 months and also of increasing difficulty of obtaining a satisfactory motion of the bowels. He stated that the cause of all this trouble was a lump in his side. This "lump" was first noticed just below the ribs on the right side about seven or eight years ago; it had gradually increased in size but had caused no pain and no symptoms beyond those already mentioned. The patient's previous history was to the effect that he had had an attack of jaundice about once every two months for the last two or three years. There was, however, no history of hepatic colic. He had never noticed anything wrong with his urine. He had never been abroad and there was no evidence of specific disease. On examination the abdomen was found to be somewhat tumid as a whole, its walls were very fat, and the right side was more prominent than the left. On palpation a large mass could be felt coming from below the right ribs and extending to about one inch from the umbilicus and one and a half inches above the intertubercular plane; it did not quite reach the middle line anywhere. The mass had a cystic feel and in the centre there was a prominent swelling on it which gave distinct fluctuation. The mass moved freely [illegible] tucked between it and [illegible] limit. With one hand in [illegible] be easily moved to and fro between them. Light percussion gave an absolutely dull note but on heavy percussion the bowel note could be obtained except in the centre. There was no thrill on percussion. There was a band of resonance between this dulness and the liver dulness but no line of bowel running down in front of the mass could be made out. There was nothing abnormal to be found in the urine.

The following operation was performed on June 10th. An incision was made over the most prominent part of the mass and on opening the abdominal cavity was discovered to be a very much enlarged kidney. It was then determined to remove the kidney by the anterior method and the posterior layer of the peritoneum was cut through. In the hope of making the tumour smaller, as there was marked fluctuation, aspiration was resorted to, but no fluid came through the needle which when withdrawn was followed by some colloid material, and on further handling the mass some small hydatid cysts came out. The wound was [illegible] one and an assistant kept the anterior and posterior layers of the peritoneum together so as to prevent infection of the general peritoneal cavity. An attempt was made to dissect the cyst from the kidney but this was found to be impossible; the whole kidney was therefore excised, the adhesions being gradually cut through; and lastly the renal vessels and the ureter. The two layers of peritoneum were then sewn together and the peritoneal cavity was shut off; the wound was then well washed out with boric acid lotion, the large cavity was left plugged with gauze, and the abdominal walls were closed. The patient was collapsed when taken back to bed and received an injection of two and a half pints of normal saline solution. On June 11th, under general anæsthesia produced by ethyl chloride, the gauze was removed and an [illegible] tube was introduced. The patient at that time felt very well and was free from pain. On the 12th he began to show signs of collapse in the afternoon and died in the evening notwithstanding all kinds of stimulation.

Remarks by Dr. Wright.—The case seems to be one of interest as, according to statistics, hydatids of the kidney are comparatively rare. The long duration of the tumour with no symptoms till the last few months and the fact that the patient had never been out of England and Wales are also deserving of attention. I am indebted to Dr. Paton, under whose care the patient was admitted, for permission to publish this report.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Occurrence of Bacillus Enteritidis Gaertner in Cows' Milk —Fugent, a New Stain.—A Note on the Use of Acid Media in the Isolation of Bacillus Pestis.—On the Development and Course of the Opsonins in Cases of Acute Lobar Pneumonia.—The Variations in the Opsonic Index in Cases of Tuberculosis.

A meeting of this society was held on Jan. 17th, Dr. E. Klein, Vice-President, being in the chair.

Dr. Klein recounted a series of observations showing that in many samples of cows' milk Gaertner's bacillus was present. Amongst 39 samples of milk—derived from various farms situated in different English counties—no fewer than 10, or 25·5 per cent., contained the bacillus. The animals injected with the sediment of 300 cubic centimetres (the sediment of each sample being used for two guinea-pigs, one intraperitoneal and a second subcutaneous) developed a chronic disease consisting in enlargement of the spleen with development of miliary purulent nodules. The nodules contained an abundance of bacilli belonging to one single species, the bacillus enteritidis Gaertner, as was proved by cultures in all media, by staining, by flagella staining, by the agglutination test, and by injection and feeding of guinea-pigs and mice with cultures. It was further experimentally shown that the above chronic disease in the guinea-pig was owing to the relative scarcity of the bacilli in the milk, since by using for injection very minute doses of culture ($\frac{1}{1000}$th part or less of a cubic centimetre of 24 hours-old broth culture) the animals survived and after eight days commenced to develop the miliary nodules of the spleen; large doses ($\frac{1}{20}$th–$\frac{1}{100}$th part of a cubic centimetre of a 24-hours-old broth culture) caused acute septicæmic infection and death. It is disquieting to reflect that such milk if kept in a warm place or in the warm months of the year might be fraught with undesirable consequences to the consumers owing to milk being a good medium for the multiplication of the bacilli and owing to the fluid nature of the milk remaining unaltered during their multiplication.

Mr. F. H. Joseph made a communication on a New Stain, "Fugent," the essential ingredients being fuchsin and gentian violet. Saturated alcoholic solutions of methylene blue, gentian violet, and basic fuchsin in the porportions 4 : 5 : 3 were allowed to mature for about one month and were then found to be stable. One part of this stock diluted with two parts of water constituted the stain. Capsules of bacteria were stained in 45 seconds of a light violet tint, the bacteria themselves being of a deep red colour. The stain had given excellent results with bacillus pestis.

The Secretary read a communication by Mr. W. C. C. Pakes and Mr. Joseph on the Use of Acid Media in the Isolation of Bacillus Pestis. Where bacillus pestis occurred in combination with pneumococcus it was often desirable to exclude the latter and this could best be done by cultivating the mixture in a bouillon with an acidity of + 25 or + 30 (Eyre's method). With this degree of acidity no growths of pneumococcus were obtained, although the acidity might be carried to + 40 before the growth of plague bacillus was inhibited.

Dr. G. G. Macdonald read a paper on the Course of the Opsonins in Cases of Acute Lobar Pneumonia. The methods used were those described by Wright and by measuring the opsonic value from day to day, using as a control the serum of a normal individual, he found that at the onset of the disease and during the pre-critical rise of temperature the opsonic content of the serum was less than that in normal serum. With the critical defervescence the opsonic content rapidly increased, passing the normal and sometimes reaching an opsonic index of 1·6. In agreement with Wright he found that the body in the normal serum sensitising the pneumococcus was thermolabile, being destroyed in 15 minutes at 60° C.

Dr. W. Bulloch made a communication on the Variations of the Tuberculous Opsonic Content in the Serum of Patients suffering from Different Forms of Tuberculosis. As a control he first determined the variations in a series of 20 healthy students and 17 hospital nurses. In comparison with his own serum as unity the variations ranged between 0·8 and 1·2. He then detailed the results of the examination of 113 cases of lupus, 19 cases of the medical forms of tubercle, and 10 cases of surgical tuberculosis. Of the medical cases most were patients who were undergoing sanatorium treatment or had been under such treatment. 65 per cent. of the patients suffering from lupus showed an opsonic index below 0·8 and in a general way there was a correspondence between a low opsonic index and a failure to cure by means of the Finsen light. The opsonic index of cases of pulmonary tuberculosis was very variable, figures being often attained considerably above the normal. A large number of cases of "arrest" or "cure" of early pulmonary tuberculosis showed an opsonic index considerably below the normal. Cases of chronic tuberculosis of bone might be above the normal but where the disease was rapidly progressing the index was for the most part found to be low.—Dr. A. E. Wright asked whether Dr. Bulloch had examined the opsonic power of women, for he had found that the opsonic power was very considerably lowered during the period of menstruation. There was also a striking difference in the opsonic reaction in cases of tubercle of the skin and chronic forms of tuberculosis of the lungs. In the former condition, of some 18 cases examined all were below the normal, whereas in the latter the opsonic power might rise to as high as 2, the normal being 1. In periods of ill-health the opsonic power fell to a very striking degree, even so low as 0·15 or 0·3.

CLINICAL SOCIETY OF LONDON.

Three Cases of Acute Ascending Paralysis in the course of Chronic Cystitis.—A Case of Accidental Electrocution causing Extensive Gangrene of all the Extremities.

A meeting of this society was held on Jan. 13th, Dr. Frederick Taylor, the President, being in the chair.

Mr. Jonathan Hutchinson, jun., showed a case of Intracranial Resection of the Second Division of the Fifth Nerve two years after operation, with complete relief from symptoms.

Dr. T. J. Walker (Peterborough) described three cases of Acute Ascending Paralysis in Cases of Chronic Cystitis. He said that he had had in his practice three cases of long-standing chronic cystitis which had terminated fatally by a most rapid acute ascending paralysis. The first case was that of a man who at the age of 15 years injured his urethra by falling astride a rail and who was under treatment for recurrent stricture and chronic cystitis from the age of 25 to 40 years but was able to follow his work. An exacerbation of the chronic cystitis had occurred about a month previous to his final attack for which he was under treatment when in the course of a night the patient felt numbness in the feet and some loss of power in the legs. When seen the next morning there was paresis of the limbs up to the thighs and by that evening paralysis had extended upwards to the arms and thorax, the breathing became embarrassed, and he died 18 hours after the onset of the paralytic symptoms. There was no necropsy. The second case was that of a man who was seen when aged 52 years with a stricture of the urinary meatus for which he had sought relief only when retention and cystitis had made his life intolerable. For the following ten years the patient continued to have cystitis. At the age of 62 years an exacerbation of the chronic cystitis occurred and this had been present for four days but without retention, when in the early morning the patient experienced uncomfortable sensations and some muscular feebleness in the limbs. At mid-day there were distinct signs of paraplegia; on the following day there was considerable progress of the paralysis, and he died 48 hours after the first sign of its commencement There was no necropsy The third case was that of a man aged 67 years who had suffered for many years from chronic cystitis and for the previous three months had required catheterisation on account of prostatic disease He had been confined to his bed for some time, when on getting out he appeared feeble and unsteady Twelve hours later there were distinct signs of paralysis of the arms and the patient died 18 hours after the first onset of the paralytic symptoms There was no necropsy Dr Walker referred to a case termed urinary paraplegia by Stanley of a man admitted into St Bartholomew's Hospital under Earle with gonorrhœa and phimosis who died three weeks later 12 hours after paraplegia had set in Another case occurred under Dr Saunders in Birmingham Dr Walker then discussed the pathology of Landry's paralysis and concluded that the connexion was not a reflex nervous one but an extension of microbes from the bladder to the spinal cord —Mr R CLEMENT LUCAS suggested that the chronic cystitis was of such long standing that the patient might have been affected with some other disease and that the spinal symptoms did not stand in causal relation to the cystitis The cases were so isolated that he was inclined to think that the paralytic affection had no connexion with the chronic cystitis —Dr E FARQUHAR BUZZARD said that the cases recorded by Dr Walker were correctly called acute ascending paralysis but doubted whether the term Landry's paralysis should be given them in the absence of more detailed clinical notes and in the absence of post mortem examinations He was inclined to believe that they were probably examples of acute ascending meningo myelitis which had been shown to occur as the result of infection of the spinal cord by a variety of different organisms —Mr W G SPENCER said that experimentally animals inoculated with hydrophobia died from an ascending paralysis This was probably but one of many toxins which might produce ascending paralysis —Dr WALKER replied

Mr CLEMENT I [illegible] cution causing F [illegible] and Death on t [illegible] was a strong well built lad 15½ year of age, who was employed at the London Electric Supply Corporation's station in the Blackfriars road The electricity which is generated at Deptford is received at this station at a high potential pressure and is distributed in smaller amounts to the surrounding districts The maximum pressure is 10 000 volts On either side of the room are placed barrel shaped "transformers about four feet six inches in height and when those on one side are "alive, or in use those on the other side are dead or uncharged The lad mounted one of those which were dead to dust some horizontal slabs of slate above them When about to descend the iron plates on the soles of his boots caused him to slip on the iron of the "dead transformer and over balancing he clutched at the slate but missed it and his right hand came in contact with the main cable carrying the 10 000 volts A man attracted by the flash and roar of the escaping current looked round and saw the lad rigid between the terminals and the transformer He ran across and caught him as he fell The current was not passing through him it was thought more than 30 seconds When laid on the ground the youth was rigid and apparently lifeless The limbs were burnt swollen and stiff Respiration had ceased and no pulse could be felt Artificial respiration was immediately started and this with vigorous rubbing of the body, brought about recovery of consciousness When taken to the hospital shortly after he showed signs of shock and all his limbs were gangrenous The right hand was dead white tightly flexed and the forearm was supinated and the arm [illegible] a up to the shoulder No pulse [illegible] ist or ankle Below the elbow [illegible] was crimson and peeling Both feet were badly burnt anæsthesia and paralysis extending up four inches above the ankles There was an everted wound in front of the left axilla as if an escape to the metal of a brace had taken place there The left hand suffered less and [illegible]

deltoid flap and the uninjured skin on the inner side of the axilla The artery was found thrombosed as high as the superior profunda branch The patient bore this operation well and on the following day had strength enough to sit up in bed Three days after the amputation and the sixth from the accident it was evident that in spite of antiseptic applications the gangrene of the feet and the legs was spreading and the patient was feeling restless and the temperature had risen to 101 4° F Mr Lucas therefore determined to amputate both legs and this was done simultaneously In the left leg œdema was found extending up among the muscles almost to the knee This double amputation was borne well and the wound at the shoulder progressed very favourably but two days later *symptoms* of toxic infection appeared and the patient became very restless his temperature rising to 104 2° and on the ninth day after the accident he died Two men were killed at this station eight years ago by the 10 000 volt current, one having gone to the assistance of the other The electrical superintendent engineer Mr E H Baker gave some interesting observations of his own which Mr Lucas incorporated in his paper and Mr Lucas alluded to several other cases recently reported for the most part from crossing live rails on electric railways —Mr F ASPINAL said that speaking as an electrical engineer, he thought that medical men were frequently handicapped in not knowing what had occurred in their cases of injury from electric currents He divided the accidents as liable to occur into the following broad classes (1) from high tension current when the victim made good contact, (2) from high tension current with bad contact, (3) from low tension current with good contact, and (4) from low tension current with bad contact He said that all currents above 750 volts should be considered as high tension The voltage was not the chief factor determining the effect produced by the current but it depended to a far greater extent on a good or bad contact He pointed out that patients severely burnt by the current did not suffer so much from shock as cases in which there was but little sign of external injury He described the "cry which he thought was almost peculiar to these injuries as an inspiratory shriek He then stated that when an arc was formed metals became volatilised and suggested that the inhalation of these vapours might cause death —Dr W J HARRIS said that the fatal effects of a current depended not on the voltage but on the horse power behind Death might follow a shock from a low voltage current and recovery might occur when a current of enormous voltage had passed through the body As an instance of the former he quoted the case of a man who was killed at the Fulham baths by a current of 250 volts and of the latter the case of a man who at the Niagara Fall station had the full current pass through the body The important factor in the cause of death was the amount of current which passed through the body He agreed with the last speaker that if there was burning of the skin there was as a rule less shock Mr SPENCER read for Dr S JELLINEK (Vienna) the following remarks Electrical currents were harmful according to the tension of the current and the resistance of the human body A tension of 100 volts demanded precautions a tension of 200 volts and more might be dangerous and a tension of 500 volts might be fatal But the harmful character of the tension was affected by the resistance A man was killed near Prague by a current of 95 volts when standing barefooted in a mixture of potash and sugar On the other hand an electrical employé in Vienna though much injured was not killed by a current of 5500 volts Under resistance there was to be considered the resistance of entry and the resistance of exit As regards the resistance of entry there was the condition of the clothes dry or wet or of the skin The dry horny palm of a workman might present a resistance of as much as 100 000 ohms soft moist skin also lesions of the skin had a very much diminished resistance, whilst the resistance of the mucous membrane of the mouth fell below 1000 ohms The resistance of exit depended upon the nature of the ground, also as it was usually the feet which connect with the ground the covering of the feet An electrical employé might come in contact with currents of high tension and do so with impunity if the feet were covered [illegible] se of the workman [illegible] otash and sugar the [illegible] The condition of the ground was most important, in private houses and some mills the ground formed a good protection, mineral acid factories and coal mines on the other hand especially favoured the occurrence of an accident In making rules for the prevention of accidents rooms and shops containing electrical installations should be distinguished according to the tension of the current and the nature of the ground, into "the safe" and "the dangerous."—Mr. LUCAS replied.

OBSTETRICAL SOCIETY OF LONDON.

Causation of Puerperal Infections.—Vaginal Hysterectomy in the Puerperium.

A MEETING of this society was held on Jan. 4th, Dr. EDWARD MALINS, the President, being in the chair.

Mr. A. G. R. FOULERTON and Dr. W. F. VICTOR BONNEY communicated a paper entitled "An Investigation into the Causation of Puerperal Infections." They said that they had examined the contents of the uterus: (1) in 12 cases in which the puerperium was normal, examination being made from the third to the tenth day after normal labour; and (2) in 54 cases of either miscarriage or labour at full term in which fever occurred. They had also made a bacteriological examination of the cervical secretion in 30 non-pregnant women who were suffering from vaginal discharge. The method of obtaining the contents of the uterus for examination was as follows. A large glass tube, of the shape and dimensions of an intra-uterine douche tube, served as a sheath for a wire with a plug of sterilised cotton-wool at its extremity. The upper end of the glass tube was covered with a cap of cotton-wool. After sterilisation of the apparatus the cap of cotton-wool was dipped in a mixture of melted paraffin and thymol. After the glass tube had been introduced into the lower part of the uterus the cotton-wool cap was withdrawn by means of a piece of string, the wire carrying the sterilised plug of cotton-wool was then pushed up to the fundus, and a sample of the contents of the uterus was thus obtained. The following was the result of the bacteriological examinations. Firstly, as regards the contents of the uterus in the normal puerperium. In all 12 cases examined the contents of the uterus proved sterile of bacteria. Others had obtained similar results, but others, again, had found certain bacteria in the uterus in the course of normal puerperia. Vogel believed that towards the end of the puerperium certain bacteria might invade the uterus without producing any symptoms. Mr. Foulerton and Dr. Bonney said that the matter could not be regarded as determined one way or another. The series of cases examined by them was too limited to be taken as a proof of the sterility of the uterus in the normal puerperium but they considered that the weight of previously published evidence was in favour of sterility. Secondly, as regards the contents of the uterus in cases of puerperal fever and in fever after miscarriage. 54 cases in all were examined—six of miscarriage and 48 of labour at full term. Clinically the cases could be separated into three groups—A. Cases with severe symptoms, terminating in death. B. Cases with severe symptoms, terminating in recovery. C. Slight fever cases (i.e., with a temperature not exceeding 102° F.). Out of these 54 cases the uterus was apparently sterile of bacteria in 15; bacteria of one kind or another were found in the remaining 39.

	Sterile.	Bacteria. found.	Total.
Group A.—Miscarriage	—	2	
Labour at full term	—	12	14
Group B.—Miscarriage	—	4	
Labour at full term	5	17	26
Group C.	10	4	14
Total			54

The bacteria found were :—

	Cases.	Total.
Streptococci, in pure culture	10	
,, with other bacteria	15	25
Micrococcus pneumoniæ, in pure culture	1	
,, ,, with other bacteria	3	
? ,, ,, (not fully identified)	2	6
Staphylococcus pyogenes aureus		1
,, ,, albus		3
A diplococcus (—Gram), not the gonococcus		2
A diphtheroid bacillus		2
Total		39

An examination of the cervical secretion in non-pregnant women with vaginal discharge was made in 30 cases with the following results. Cultures of various bacteria were obtained in 16, bacteria were demonstrated by microscopic examination but attempts at culture failed in three, attempts at culture failed and no bacteria were seen on microscopic examination in nine, and attempts at culture failed and no microscopic examination was made in two; total, 30. Amongst the bacteria found in 16 cases were staphylococcus pyogenes aureus, staphylococcus pyogenes albus, micrococcus gonorrhœæ, bacillus coli communis, a "diphtheroid" bacillus, a diplococcus (— Gram, but not micrococcus gonorrhœæ), and an encapsulated diplococcus (+ Gram ? micrococcus pneumoniæ). The general results of the bacteriological examination which had been made were as follows: (1) streptococci were present in the uterus in 25 out of 39 cases in which cultures from the contents of the uterus were obtained; (2) streptococci were present in the vagina in two cases out of 17 in which the contents of the uterus were apparently sterile of bacteria; (3) streptococci were present in the uterus in 25 out of 40 cases of severe fever, and in the vaginal secretion in two out of five similar cases in which the contents of the uterus were sterile of bacteria; (4) out of 14 cases of "slight" fever the contents of the uterus were sterile of bacteria in ten, and in four cultures of bacteria were obtained but not a streptococcus; (5) of the 15 cases in which the contents of the uterus were sterile of bacteria a marked proportion were primiparæ presenting considerable lacerations of the cervix or perineum; (6) the presence of micrococcus pneumoniæ was proved in four of the cases and in two others it was probably present; (7) in the present series the absence of micrococcus gonorrhœæ and anaerobic organisms was noticeable; and (8) in the series of cases in which the cervical secretion was examined proof was obtained of the presence in the cervical canal of non-pregnant women of bacteria which had also been found in puerperal infections of the uterus but in no case were streptococci found. Mr. Foulerton and Dr. Bonney summarised the pathology of puerperal infections as follows: 1. Puerperal fevers may be caused by (*a*) primary infection of lacerations of the vaginal walls or perineal tissues (with secondary infection of the uterus sometimes); and (*b*) primary infection of the contents of the uterus or of the placental site. 2. The processes concerned in the production of puerperal fevers might be classified as: (*a*) primary, vaginal, or perineal infection (local infection + toxæmia; local infection + toxæmia + general infection); and (*b*) primary infection of the uterus (local infection + toxæmia; local infection + toxæmia + general infection). Their general conclusions were as follows: (1) puerperal fever when bacteriological proof of the nature of the infection was wanting should be treated as being due to streptococcic infection; (2) active curetting of the uterus in puerperal infections was not to be advised; (3) the most satisfactory treatment for streptococcic infections of the uterus was comprised in the administration of an appropriate antistreptococcic serum, and digital exploration and clearing out of the contents of the uterus, followed by intra-uterine douches; (4) the fever following a streptococcic infection of the uterus might be transient and might subside within 48 hours without any special treatment—a fact to be remembered when dealing with the conveyance of infection; (5) autogenetic infection was probably sometimes a cause of puerperal fevers, but the use of vaginal douching before labour with the view of obtaining asepsis was not advisable; (6) in this series of cases bacterial invasion of the uterus had always been marked by severe symptoms with abrupt rise of temperature to 102° or higher; and (7) in the majority of the cases in which the contents of the uterus were sterile and there were severe lacerations of the cervix or perineum the symptoms were very much less severe and the temperature did not rise to above 102°—Dr. P. HORROCKS said that the fact that the contents of the uterus were found sterile in every instance where the puerperium was normal constituted an argument against interference in labour, such as routine syringing, vaginal or uterine. He remarked on the absence of any distinction between septicæmia and sapræmia in the classification adopted by Mr. Foulerton and Dr. Bonney who had taken the amount of fever as the sole guide to the severity of the illness. The presence or absence of an offensive discharge was of the greatest moment. In the grave form or puerperal septicæmia proper the lochia were not offensive but were scanty or suppressed and sweet; whereas in sapræmia the *lochia were not scanty but were offensive, and when the* offending products were cleared out of the uterus the temperature, as a rule, rapidly fell to normal and the patient recovered. Doubtless in some cases the patient suffered from a mixed sepsis and then the clearing-out process was not followed by the improvement usually expected.—Dr. **Amand J. M. Routh** agreed that streptococci were the most frequent cause of the severer forms of puerperal fever. He had also found many cases of fever where the contents of the uterus were proved to be sterile. Was it possible that some of these were infected by moulds, yeasts, or forms of streptothrix, all of which might cause diseases in women? He had little faith in antistreptococcic serum, having seen only one case recover by its use, and had much more reliance on tincture of perchloride of iron in 20- or 30-drop doses every two or three hours.—Dr. A. W. **Sikes** said that he had been much impressed with the good results obtained by early digital exploration followed by intra-uterine douching, but he considered that the results from antistreptococcic serum were often unsatisfactory.—Dr. R. **Boxall** said that as a rule active curetting of the uterus was not to be recommended. As regards the use of antistreptococcic serum he still preserved an open mind. There were many disadvantages in its use and he had seen considerable danger follow but never appreciable improvement. Inasmuch as it had been proved that at the time of labour the vagina might contain pathogenic organisms, the presence of which was often unsuspected and difficult to detect, he adhered to the practice of douching the vagina early in the course of labour with a view to preventing the possibility of autogenetic infection on the same principle that he took measures to disinfect and render sterile the skin of the abdomen before performing laparotomy.—Dr. **Arnold W. W. Lea** said that he had carried out a similar investigation in 18 consecutive cases of severe puerperal infection and with much the same result as Mr. Foulerton and Dr. Bonney. He had also examined the blood in 14 of these cases. In two cases only were streptococci discovered and both ended fatally. He believed that in many cases of fatal infection the blood remained [illegible] and rapidly fatal types and might account for the frequent failure of the serum treatment; the streptococci developed *in the lymphatic vessels and tissues of the pelvis, producing* toxæmia, but the serum was powerless to act directly upon them as it could only be injected into the blood stream.—Mr. **Foulerton**, in reply, explained that most of the cases which were clinically included under the term "sapræmia" fell into the pathological category of local infection + toxæmia, occasionally with general infection superadded. He thought it unlikely that micrococcus gonorrhœæ, yeast parasites, or streptothrix had been overlooked in any of their cases. Too much importance had, he felt sure, been attributed to micrococcus gonorrhœæ as a cause of puerperal infection. Both he and Dr. Bonney held very strongly that an immense proportion of the cases of streptococcic puerperal fever was avoidable and the more nearly the conditions of general obstetrical practice approximated to those of a properly conducted lying-in hospital the less frequent would streptococcic infection be and the lower the mortality from puerperal fever. While recognising the difficulties associated with serum treatment, there could not be any doubt in his mind that an antistreptococcic serum did act as a specific cure in some cases of puerperal fever.

Dr. **Lea** read a paper on Vaginal Hysterectomy in the Puerperium for Sepsis (?) due to Suppuration of a Myoma. He said that curetting was performed without beneficial result. Pyrexia continued with occasional rigors but there was no peritonitis. The uterus was removed by means of ligatures per vaginam seven weeks after delivery. Both uterine appendages and a portion of omentum, all of which were implicated, were removed at the same time. A glass vaginal drainage-tube was used. The temperature fell to normal within a week and complete recovery followed. Pus from the tumour showed streptococci and bacillus coli communis.

EDINBURGH OBSTETRICAL SOCIETY.

Climacteric Hæmorrhage.—Bier's Hyperæmic Treatment.—Fatal Prolapsus Uteri.

A meeting of this society was held on Jan. 11th, Professor A. R. **Simpson**, Vice-President, being in the chair.

Dr. A. H. *Freeland Barbour* read a paper on Climacteric Hæmorrhage due to Sclerosis of the Uterine Vessels. Hæmorrhage at the climacteric was often the sign of malignant disease and should be investigated early, as the only hope lay in early operation. Once pain or fœtid discharge was present the chance of a successful operation was lost. Hæmorrhage after abortion might occur at the climacteric as at any other time. The following case threw light on another cause which had not received sufficient attention. The patient, aged 46 years, had been a healthy woman all her life till four and a half months before admission to hospital. There were no evidence of hereditary or constitutional disease and no history of alcoholism. She had had nine full-time children and two miscarriages after her fourth and fifth children; her last child was born when she was 43 years old. Her menses were always regular and never excessive till 19 weeks before her admission to hospital when a severe hæmorrhage began on the day of her expected period and continued for 16 weeks. The amount varied: sometimes only a little passed, at others severe flooding took place which confined her to bed. She consulted a medical man who gave her medicine which evidently stopped the hæmorrhage for three weeks before admission. On admission she was anæmic and cachectic, her appearance suggesting malignant disease. The pulse was small and feeble; no thickening of the radial or other arteries was evident. The uterus was enlarged, irregular in shape, and about four inches in vertical measurement. As the patient was not in a fit state to stand a preliminary curetting it was decided to perform hysterectomy as soon as she was fit for it. Owing to the size of the uterus the abdominal route was chosen and panhysterectomy was done, as malignant disease of the body was diagnosed. The patient had phlebitis after the operation but she did well and left the hospital seven weeks later. On examining the specimen a plexus of wide vessels with markedly thickened walls was found in each broad ligament; the vessels anastomosed freely with each other. One of these vessels measured 0·5 centimetre in diameter. The walls of the uterus measured 2·5 centimetres in thickness in the middle of the body; from the cut surface the vessels stood out prominently and had apparently thickened walls; they were most marked in the outer third. The mucosa was [illegible] measured one millimetre in [illegible] were normal. The uterine [illegible] from normal. The first case recorded resembling this one was by Pichevin and Petit in 1895; two years later Reinecke reported four cases of hysterectomy, all showing changes in the vessels. Bland-Sutton in 1899 described a similar condition in three cases and Pozzi two cases in the same year. Simmonds in 1901 performed hysterectomy for continuous hæmorrhage *resisting all treatment*, where the only pathological change found was marked sclerosis of the uterine artery. Marisani in 1901 had a case which he [illegible] sclerosis and regarded it as a manifesta- [illegible] tion was different from "apoplexia [illegible] menopause, where calcareous and senile degeneration of the uterine arteries had been found. It could not be diagnosed during life, though by curetting malignant disease or retained products of conception could *be excluded*. The only treatment was hysterectomy; ergotin and curetting did not touch the affected vessels.—Professor **Simpson**, Dr. **Jessie M. MacGregor**, and Dr. F. W. N. **Haultain** discussed the paper.

Dr. E. W. **Scott Carmichael** read a paper on the Application of Bier's Hyperæmic Treatment to Gynæcological Disease. Bier found by experimental and clinical observations that hyperæmia induced in a diseased part brought about distinct changes, salutary or otherwise, in the tissues *according to* the pathological process present. An acute hyperæmia was produced by exposing the part of the body to a high temperature, thereby increasing the rate of the flow of blood to it by dilating the capillaries; a passive congestion was induced by obstructing the venous return, thereby producing more or less stasis and congestion in the blood-vessels. It was only the form [illegible] abdominal conditions. Bier [illegible] produced in a limb by e[illegible] apparatus to hot dry air had a bactericidal action; it also had the power of alleviating pain, of promoting absorption, of loosening adhesions, and of stimulating general nutrition and regenerative processes. In all forms of affections of the joints—gonorrhœal, rheumatic, or septic—it soothed pain and markedly promoted absorption and loosened adhesions. Martin applied this treatment to inflammations of the pelvic organs, especially when there was much exudation, and in these cases it had superseded practically every other method of treatment, such as ichthyol, glycerine, iodine, &c. If there was a tendency to suppuration the hot-air treatment hastened it rapidly, while in the chronic forms it favoured absorption. Great relief was obtained locally and the general condition rapidly improved.

Mr. G. F. BARBOUR SIMPSON read a paper on a case of Fatal Complete Irreducible Prolapsus Uteri, the specimen of which was shown and illustrated with photographs. The patient was 42 years of age, a laundress by occupation, and was admitted into hospital in September last complaining of falling down of the womb of several months' duration. There was a mass projecting from the vulva five inches long and four inches wide and constricted at its base by the vulva. The whole mass was extremely sensitive on manipulation. A finger in the rectum detected the fundus of the uterus near the vulva; a catheter passed into the bladder showed that the whole organ was external to the vulva. Reposition was twice attempted, once under chloroform, but without success. The patient died a fortnight after admission with symptoms of general septicæmia. It was remarkable that she suffered apparently little inconvenience till a fortnight before admission. Post mortem an abscess cavity was discovered extending from the utero-vesical pouch upwards into the peritoneal cavity for a distance of eight inches; the intestines were closely matted together with numerous adhesions as the result of chronic peritonitis. These adhesions had rendered any attempts at reposition impossible —Dr. HAULTAIN and Professor SIMPSON discussed the paper.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 9th, Dr. A. Bronner being in the chair.—The following cases and pathological specimens were shown:—Dr. J. Gordon Sharp: Urali Plant and various Poisons and Poisoned Arrows.—Dr. J. B. Hellier (with Dr. J. A. Hargreaves): Placenta from a case of Premature Labour. Dr. Douglas Seaton: Dermoid Cyst of the Ovary.—Mr. H. Littlewood: (1) Excision of the Elbow for Old Dislocation six weeks after operation; and (2) Intussusception, entero-ileo-cæcal variety. —Mr. H. Secker Walker: (1) A case of High Myopia, – 35 D., with Choroidal Changes; (2) a case of Radical Mastoid Operation complicated by Sinus Phlebitis; and (3) a case of Chronic Otorrhœa treated by the Mastoid Operation with subsequent skin-grafting.—Dr. A. E. Porter: Some Pathological Specimens from the Slaughter-house.—Dr. A. G. Barrs: A case of Malarial Anæmia with Enlargement of the Liver and the Spleen.—Dr. Carlton Oldfield: Specimen of Oxalate Calculus removed by Nephrolithotomy.—Dr. E. F. Trevelyan: (1) A case of Aphasia nine months after its onset; (2) a case of Tabes Dorsalis with exaggerated knee-jerks; (3) a doubtful case of Multiple Sclerosis in a woman; (4) a case of Muscular Atrophy in a girl, aged 17 years; (5) a case of Limited Muscular Atrophy in a man, aged 73 years; (6) two cases of Ulnar Paralysis; (7) a Brain from a case of acute febrile pulmonary tuberculosis in a lad aged 19 years, in whom fits occurred during the last two weeks of life; and (8) a specimen of Blood from a case of Myelogenous Leukæmia in a man, aged 24 years.—Mr. R. Lawford Knaggs: (1) Epithelioma of the Bladder; and (2) (with Dr. C. M. Chadwick) Malignant Ulcer of the Rectum fungating into the peritoneum and into the bladder.—Dr. L. A. Rowden: Case of Hyperæmia of the Hands and the Face; diagnosis?—Mr. J. Basil Hall read notes of a case of Spasmodic Torticollis treated by resection of the spinal accessory and posterior cervical nerves. The patient, a quarryman, aged 37 years, had suffered from otorrhœa on the right side 20 years previously. The otorrhœa ceased completely eight years ago. He then had a slight tremor of the head. One year ago tinnitus commenced and he became quite deaf in the right ear. Soon after spasmodic torticollis appeared which had steadily grown more violent until he became quite incapacitated. When first seen he was suffering severely from spasm of the right sterno-mastoid and the left retrocollic muscles. The right retrocollic muscles were also involved but to a lesser extent. The movements, which were very violent, abated when he lay down and ceased altogether during sleep. The affected muscles were much hypertrophied. There was no ocular defect. The right tympanic membrane was practically destroyed. On Nov. 12th, 1903, an inch of the right spinal accessory and the first, second, and third posterior cervical nerves of the left side were excised. The patient's condition was much improved but a good deal of spasm remained in the right retrocollic muscles. He remained for two months under observation when, as no further improvement took place, the first, second, and third posterior cervical nerves on the right side were excised. The patient left the hospital at the end of three weeks. There was no spasm but there was a fine tremor of the head. He was last seen 12 months after the first operation. There had been no return of the spasm. He could hold his neck erect and extend it on the trunk. The tremor remained.—Mr. B. G. A. Moynihan discussed the paper and referred to four cases in which he had performed a similar operation.—Mr. Hall replied.—Mr. W. C. Mayo drew attention to the difficulties in the administration of anæsthetics in abdominal operations due to the nervous reflexes caused by the surgeon's manipulations. When the patient had suffered much abdominal pain these reflexes were more difficult to overcome. For 18 months he had given chloretone (from 15 to 20 grains) half an hour before commencing the operation, and had found that patients took the anæsthetic better and more quickly with fewer after-effects. He drew attention to the difference of opinion as to the best anæsthetic in these cases. He had obtained good results with a mixture of ethyl chloride, 20 per cent.; chloroform, 40 per cent.; and ether, 40 per cent., given on a towel as chloroform, only faster, until the corneal reflex had nearly gone, and then changing to ether in a Clover's inhaler until the breathing was deep and regular, the pupils fairly dilated, and the muscles of the lower jaw quite relaxed. The patient was now ready for operation, for which relaxation of the abdominal muscles was the chief point. When the abdomen had been opened it was often a help to the surgeon to change to chloroform. With regard to the ethyl-chloride-chloroform-ether mixture mentioned above most patients went quietly into unconsciousness in from one and a half to six minutes with less struggling and excitement than with chloroform. There was no cyanosis or excess of mucus, the breathing was quiet and regular, and the colour was good. The anæsthesia was inclined to be of a light character. Attention was also drawn to the necessity of attending to oral sepsis for some days before the operation, thereby avoiding pneumonia; and also to the combating of shock by the use of liquor strychninæ and oxygen administered from a Hewitt's gas-bag.—Mr. Littlewood, Dr. W. McGregor Young, Mr. Moynihan, Mr. E. Ward, Mr. Hall, and Dr. Bronner discussed the paper and Mr. Mayo replied.

BRITISH GYNÆCOLOGICAL SOCIETY.—At the annual general meeting on Jan. 12th, Professor John W. Taylor, the President, being in the chair, the following officers were elected for the current year:—Honorary President: Dr. R. Barnes. President: Dr. William Alexander. Vice-Presidents: Mr. E. Stanmore Bishop, Dr. Bedford Fenwick, Mr. F. Bowreman Jessett, Dr. R. P. Ranken Lyle, Sir Arthur V. Macan, Dr. J. J. Macan, Dr. H. Macaughton-Jones, Dr. Christopher Martin, Dr. J. A. Mansell Moullin, Dr Thomas Oliver, Dr. Heywood Smith, and Mr. W. Dunnett Spanton. Honorary treasurer: Dr W. H. Slimon. Council: Dr. T. Gelston Atkins, Dr. N. T. Brewis, Mr. G. Roe Carter, Sir J. Halliday Croom, Dr. William Duncan, Dr. F. Edge, Dr. George Elder, Dr. T. J. English, Dr. J. H. Ferguson, Dr. Clement Godson, Dr. Arthur Helme, Dr. R. J. Kinkead, Dr. J. Macpherson Lawrie, Dr. Samuel Lloyd, Mr. John Padman, Dr. Ernesto Pestalozza, Dr. J. J. Redfern, Mr. Charles Ryall, Dr. R. T. Smith, Dr. J. H. Swanton, Dr. J. W. Taylor, Dr. W. Travers, Mr. H. F. Vaughan-Jackson, and Dr. Hugh Woods. Editor of the Journal: Dr. Macan. Assistant editor: Dr. Swanton. Honorary secretaries: Dr. Sol Jervois Aarons and Dr. Smallwood Savage. Auditors: Dr. C. H. Bennett and Dr. F. A. Purcell. Trustees of the property of the society: Dr. G. Granville Bantock, Dr. R. S. Fancourt Barnes, and Dr. Clement Godson.—Dr. J. Inglis Parsons showed a Double Pyosalpinx symmetrically enlarged on each side and removed without any rupture. Even in the presence of dense adhesions, by taking time and separating the adhesions from behind and below, he found it often possible to isolate and to remove both tubes without rupture.—The President then delivered his valedictory address. After reviewing the progress of gynæcology during the last year and alluding to the loss which the profession had sustained from the deaths of many eminent men, he mentioned that his association with the society, of which he became a *Foundation Fellow more than 20 years ago*, was coterminous with his work as an operating gynæcologist. During that time he had performed 1291 operations with only 85 deaths, a total mortality of 6·5 per cent. But many of the deaths were unavoidable or only indirectly due to operation. One was from apoplexy; four were cases of acute perforative peritonitis, one of which was a Cæsarean section with a child now still alive; four were moribund cases of intestinal obstruction; and 22 patients died rather from malignant disease than from the results of the operation. He had, however, to regret some early cases of sepsis and one case of death from secondary hæmorrhage. Some cases also of myomata operated on by the modified clamp operation might no doubt have been saved by more modern methods. Taught by experience, his best work had been in the last five or six years which, including a fair proportion of grave cases, showed a mortality of only 1 per cent. His experience extended over days of ignorance when hardly anything was left undone that favoured infection, over days of empirical asepsis, and the more recent ones enriched by our acquired knowledge. He attributed the greatest advantage to the recognition of the efficiency of heat in sterilisation, to the disinfection of the hands by potassium permanganate supplemented by spirit and biniodide of mercury, not only before operation but after every dangerous contact, and to the substitution of fine interlocking chain sutures of silk for ligature *en masse*. Fine silk he had found to be in time as perfectly absorbed as catgut. Pelvic hæmatocele, the so-called broad ligament hæmatoma, formerly the commonest complication of post-operative convalescence, though attributed to the use of a sharp needle, he had not found to have that origin. It was more probably due to ulcerative erosion of the vessels owing to infection from the thick silk used in tying the pedicle. The removal of the appendages for myoma he had gradually, though not entirely, abandoned in favour of abdominal or vaginal hysterectomy, and he now seldom performed that operation for gonorrhœal tubal disease, preferring systematic treatment with biniodide of mercury, which, even in cases demanding interference, when combined with the evacuation of the sacs and drainage, was generally better than the old operation. In inguinal cœliotomy by Reclus's method, by tying off a small amount of mesentery at each side of the spigot of glass at the original operation, he found that the subsequent division of the intestine was practically bloodless and not accompanied by arterial hæmorrhage, as otherwise was too often the case. *In conservative* operations some of his greatest successes had been the separation of adnexal adhesions to the intestines causing obstruction; hysteropexy and ventro-suspension were also conservative, but he had found conservative operations on the appendages disappointing. Simple prolapse of the ovary due to retro-displacement was best treated by shortening the round ligaments without opening the peritoneum. Disliking all forms of fixation he had abandoned anterior colpotomy, but had become more and more attracted by posterior colpotomy, the advantages of which were not to be overlooked even in virgins or children. The essential point in the operation, after the disinfection of the vagina, was free drainage with iodoform gauze. Vaginal ovariotomy and vaginal enucleation demanded increasing consideration.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held on Jan. 6th, Mr. C. M. Tuke, the President, being in the chair.—Dr. Z. Mennell showed a typical case of Acromegaly in a man, aged 42 years. In 1883 he enlisted in the army and his measurements were as follows: weight, 10½ stones; height, 5 feet 10½ inches; chest, 37 inches; and circumference of the head, 21 inches. From 1887 to 1902 he had constantly to get larger boots, hats, gloves, and clothing, when latterly he could not get stock sizes large enough and his measurements at present were: weight, 19 stones 3 pounds; height, 6 feet 1 inch; chest, 47 inches; and head, 25½ inches—which measurements had remained about the same during the past two years. His personal health was good, his only subjective symptom being occipital headache, with depression of spirits.—Dr. A. Morison showed: 1. A case of Old-standing Mitral Stenosis with Persistent Choreic Movements in a man, aged 76 years. At the age of 14 years he first had an attack of rheumatic fever, followed by clonic convulsive *movements of the right arm, and when 30 years old he* had a second attack which was followed by a similar affection of the left arm. 2. A man, aged 51 years, with a "Renal Heart," associated with Granular Contracted *Kidney.—Dr. J. B. Ball* exhibited a man, aged 52 years, with Tonsillar Disease of about six months' [illegible] he [illegible] u- [illegible] a [illegible] of [illegible] he [illegible] at first. A small portion of the tissue had lately been examined microscopically showing the disease to be of a malignant type. Dr. Ball considered it to be a case of combined [illegible] uggested [illegible] mercury [illegible] —Mr. G. Pernet also suggested a course of mercury under strict observation and apart from iodide of potassium.—Mr. R. W. Lloyd said that *local* mercurial treatment combined with internal administration of antisyphilitic remedies might prove useful.—Mr. J. T. Armstrong did not agree with the mercurial treatment, taking into consideration the microscopical repor[illegible] —Dr. Ball br[illegible] the notice of [illegible] occurred on the back of the right hand of a girl. It commenced as a papular rash about six months previously, the papules disappearing and leaving an indurated elevated margin around the centre which regained its normal condition.—Dr. T. Colcott Fox said that the disease was a very rare one, the etiology of which was unknown.—Mr. Pernet was of opinion that this case was not one of granuloma annulare and showed microscopical sections of the latter disease.—Mr. D. J. Armour showed a female, aged 26 years, upon whom he had operated for a Bilateral Ankylosis of the Jaw. Both condyles were found to be fused with the zygoma, forming a solid mass of bone of ivory-like hardness. The zygoma just in front of, and behind, the tuberosity and the neck of the jaw were cut through on each side and the jaw was subsequently moved several times under an anæsthetic. The patient could now separate her jaw easily and well and was able to eat solid food for the first time in her life.—Mr. Armour also showed a specimen of a Polycystic Kidney which he removed from a woman, aged 29 years, who made an uninterrupted recovery. Since the operation she had improved in health and was passing a normal amount of urine.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—A meeting of this society was held on Jan. 9th in the Faculty Hall, Professor R. Muir, the President, being in the chair.—Dr. T. K. Dalziel and Dr. J. Walker Downie described a case of Removal of the Pharynx and a Portion of the Larynx on account of Epithelioma. The growth was a very extensive one, involving a considerable area of the pharynx in its whole circumference, the posterior wall of the larynx, and the orifice of the glottis; there was also a large mass of infected glands in the right side of the neck. The operation was performed without hope of cure but for the *alleviation of the miserable state of* the patient and proved much more formidable than had been anticipated. The whole growth was removed. The œsophagus was then detached from the trachea for a distance sufficient to allow of the end being brought out and was stitched to the skin of the side of the neck for the use of the stomach tube. The patient made an uninterrupted recovery. The tracheotomy tube, which had been [illegible] removed [illegible] with was [illegible] ere being no other way of escape for it; but this stopped after two months, the salivary glands having ceased to perform their function. All food necessarily was taken through the stomach tube; it did not affect the secretion of saliva while the glands were active. Since the operation the patient had nursed her husband and her son through severe illnesses, but now, after six months of happiness and usefulness, she is dying from pressure on the air passages by a mass of glands in the right side of the root of the neck. The anæsthetic used at the operation was chloroform.—Dr. John H. Teacher and Dr. G. Burnside Buchanan showed a specimen of Multiple Carcinomata of the Intestines. The primary tumour appeared to be that situated in the rectum; there were about 20 nodules of various sizes scattered along the whole length of the great intestine and a group in the lower part of the small intestine; beside the latter there was considerable infiltration of the mesentery. The secondary nodules were situated in the submucous layer of the gut. The course of spread could not be traced.—Dr. Henry Rutherfurd showed a specimen of Multiple Carcinoma of the Great Intestine. A tumour (carcinoma) of the rectum had been removed two years previously.—Dr. D. N. Knox showed the Sac of an Encysted Infantile Hernia and read notes of two such cases. The specimen was taken from a patient, aged 72 years; the hernia had been in existence for many years and was as large as a cocoanut. The other case occurred in a child.—Dr. J. K. Kelly showed a number of specimens of Uterine Myomata and Ovarian Dermoids and read short notes of the cases.—Dr. A. Napier and Dr. John Anderson gave an account of a case of Patency of the Interventricular Septum. The orifice occupied the undefended area of the septum and measured about an inch in diameter. In spite of this considerable defect the patient enjoyed perfect health up to her seventeenth year, then manifested signs of cardiac weakness but recovered and remained well until the birth of her first child at the age of 27 years. She died soon after with symptoms suggestive of aortic incompetence.—Dr. Napier and Dr. Anderson also described a case of Tuberculous Meningitis in an adult which simulated enteric fever.

DERMATOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on Jan. 11th, Mr. Malcolm A. Morris being in the chair.—The following were among the cases exhibited:—Mr. Morris showed a young woman, 19 years of age, who had been troubled three years ago with Warts on the Backs of the Hands. These had been removed by means of the x rays and one year later telangiectases had begun to make their appearance on the situations which had been exposed and these were still increasing. The exhibitor commented on the unusually long latent period between the exposure and the development of the evil effects.—Dr. T. Colcott Fox showed a young man who had travelled all over the world and lived in almost every climate and who had first noticed four years ago a red spot on the right shin. This had enlarged very slowly without giving rise to any special symptoms and had been followed in May, 1904, by the appearance of several other spots on the same leg and the other leg and quite recently on the arm. The patches were flat and a little scaly, the centre was pale and obviously atrophic, and the margin was a little reddened. Careful examination had shown that there were no anomalies of sensation and Dr. Fox thought that there need be no apprehension of any serious disease and also that the eruption probably belonged to the class of so-called idiopathic atrophies to one of which the name of "erythromelie" had been given.—Dr. E. G. Graham Little showed a man with Widespread Lupoid Eruption on the Face affecting the whole of the nose, with patches on both cheeks and both ears. The disease had commenced six years previously with a blow on the nose. The patches were much thickened and obviously transparent and granulomatous looking, so that he thought some might consider it to be a true lupus vulgaris. A section of the diseased area was also exhibited in order to aid in the diagnosis. The opinion was generally held that the disease was lupus erythematosus.—Dr. Sale-Barker (introduced) showed an interesting group of children in whom Ringworm of the Scalp had been treated by the x rays. The method that he used was to measure the current actually passing between the terminals of the vacuum tube and to use a constant spark gap. He then gave the children rather long exposures and found that usually two were sufficient to cause epilation. He pointed out that in a case in which he had caused a total defluvium for disseminated ringworm and in which there must have been some overlapping of the exposed areas no dermatitis had resulted.—A considerable discussion took place with regard to these cases and the general opinion seemed to be that the method was now firmly established as the speediest treatment for ringworm of the head. Many members had used it in numerous instances and no member reported any untoward result, though all agreed that the greatest care must be taken.

SANATORIUMS FOR TUBERCULOSIS.—At a meeting of the board of delegates of the Hospital Saturday Fund Association, held at the offices, Gray's Inn-road, London, W.C., it was decided on the motion of Mr. Dear that a sum of £500 should be granted from the 1904 collections to the National Sanatorium Committee towards the erection of sanatoriums for tuberculous patients on a site secured near Hastings.

Reviews and Notices of Books.

Morphology and Anthropology: A Handbook for Students. By W. L. H. DUCKWORTH. Cambridge University Press. 1904. Pp. 564. Price 15*s.* net.

Studies from the Anthropological Laboratory of the Anatomy School, Cambridge. By the same Author. Cambridge University Press. 1904. Pp. 291. Price 10*s.* net.

THE first of the two volumes which we notice here is published at a not inappropriate time. The recent establishment of a Board of Human Anatomy and Morphology in the University of London, dealing with regulations as to the inclusion of this subject in the honours list of the University, should produce, if it has not already produced, some quickening of the really scientific study of man as opposed to the older "professional" anatomy necessary for the acquirement of medical and surgical degrees and qualifications. For the beginner in this branch of biology, armed with a general knowledge of comparative anatomy, Mr. Duckworth's handbook should prove useful. This general armature is necessary but it is not unreasonable for the author to assume its existence, for no person undertakes the study of man at present without a previous grounding in the essentials of biology. Mr. Duckworth, however, starts with a brief reference to mammals in general and then takes the reader more and more into his confidence as he advances upwards in climbing with them the tree of mammalian life: until after a longer account of the lemurs and a still more prolonged statement of the anatomical characters of the monkeys he expands into a detailed *résumé* of the anatomical characters of the species *homo sapiens* and of the several races into which our species has been subdivided. This account, however, is not at all like that of the current text-books of human anatomy such as Quain's and Gray's. It is anthropological rather than anatomical; in fact, the author limits himself to the consideration of those characters which afford racial distinctions or which point to affinity with the apes. The title of the book, indeed, implies its scope, for it is obviously taken from the *Zeitschrift fur Morphologie und Anthropologie*, a journal devoted to physical anthropology and the structure of the apes. The origin of this muscle and the insertion of that are, in fact, of no interest save in so far as they recall by their variations a similar state of affairs in the anthropoid apes or appear to furnish a valid racial character among men; so, too, with brain and sinew, bone and gut.

The beginnings of this study are to be found in a memoir published in 1699 by Edward Tyson with the aid of the Royal Society. In this work that author, the first of anthropologists, compared the bodily structure of the chimpanzee with that of man and one of the lower apes. It is a curious fact, which may be commented upon in passing, that Tyson termed his chimpanzee "orang outan sive homo sylvestris." The Latin is a translation of Malay words but, as everybody knows, the orang is a totally different beast from the chimpanzee. The latter is a native of Africa and the former is Malayan. This confusion between two entirely different anthropoid apes has been lately further confounded; for the Hon. Walter Rothschild in exhibiting to the Zoological Society a magnificent series of skins and skeletons of gorillas and chimpanzees took occasion to point out that the proper name of the chimpanzee—i.e., the name which has priority—is *Simia satyrus*, a name which has hitherto been applied only to the orang of Borneo. Since Tyson the study has been forwarded by most of the great anatomists of the eighteenth and the beginning of the nineteenth centuries, and there are plenty of workers to-day whom to enumerate would be a long task and from whom to select would be invidious. The earliest text book of this subject, or at least the earliest impressive *résumé*, is Huxley s well known "Man's Place in Nature " But such text books are so few that Mr Duckworth may be congratulated in occupying a part of a by no means well filled area The chief fault we find with the book is the coarseness of the majority of the illustrations which, considering its price, does not reflect credit upon the Cambridge University Press

The same remark applies, though not to so large an extent, to the second of the volumes which we notice in this column This consists of a number of separate papers upon anthropology and the anatomy of various primates which have been partly published elsewhere and are partly printed here for the first time Many of the illustrations, indeed, of this volume are repeated in the handbook, notably those of the brains of various lemurs and apes In describing these brains Mr Duckworth initiates a useful plan In zoological matters a species is described from a "type,' which is the actual skin or, it may be, skull or skeleton upon which the species was founded Future descriptions are referred to this type for likenesses and differences In an analogous way the author of the book under review considers the splendid catalogue of brains in the Museum of the College of Surgeons by Dr Elliott Smith to represent the types of the several brains described It would be capital if anatomists generally would adopt this or some such plan in dealing with the brains of different species Then a vast deal of ink and paper would be preserved for future use A memoir dealing with the cerebral convolutions of a given animal could be much abbreviated As it is, the literature relating to the brain is so extensive that it is difficult for those interested in comparative anatómy generally to include the study of brains Most of the memoirs in this volume deal with craniology and many are based upon human skulls in the museum at Cambridge

Diseases of the Heart A Clinical Text book for the Use of Students and Practitioners of Medicine By EDMUND HENRY COLBECK, B A, M D, B C Cantab F R C P Lond, D P H Cantab Physician to Out patients at the City of London Hospital for Diseases of the Chest Victoria park, E, &c With 43 illustrations Second edition revised and enlarged London Henry Kimpton 1904 Pp 350 Price 7*s* 6*d* net

THE appearance of a second edition of Dr Colbeck s book within a comparatively short time of its original publication shows that it has won favour with those for whom it was written and we think that it deserves the success which it has attained Without making any pretensions to originality or novelty it yet presents in a clear and readable form the accepted views with regard to the phenomena and the treatment of cardiac disease The book is dedicated to Sir William Broadbent and his teaching is reflected in many respects

After a short account of the anatomy and the physiology of the heart the author deals at some length with methods of diagnosis giving a separate chapter to the consideration of the pulse Next follows an account of congenital affections of the heart, in which perhaps additional clearness might have been gained by the insertion of diagrams illustrating the complicated process of development of this organ, always difficult to render intelligible to the learner Diseases of the pericardium follow, and here we may remark that writers upon cardiac disease almost invariably speak of paracentesis pericardii as a simple operation free from risk In view of the very great difficulty which may exist in distinguishing an enlarged and feebly acting heart from a pericardial effusion, it would seem better to advise beginners at all events to exercise great discretion in the matter Dr Colbeck next deals with acute and chronic endocarditis, with the various forms of valvular disease, and with affections of the myocardium It would, perhaps, be well if more care were taken by teachers to point out to students that hypertrophy of the heart is not in itself a diseased condition but rather an attempt to compensate defects existing in the circulatory apparatus The book ends with chapters on angina pectoris and functional diseases of the heart

The advice as to treatment for various kinds of cardiac lesions is generally prudent and sensible We are glad to see that the author has not been infected with that distrust of alcohol as a remedy which is so sedulously fostered by a certain school of modern writers That it is a valuable drug when used with proper discretion we have no doubt whatever The sections on treatment might, perhaps, have been made still more instructive by insistence here and there upon small practical points, e g, the influence of posture as an aid in the removal of dropsy, raising of the head of the bed or allowing the legs of the patient to hang down while he reclines propped up in a chair being often most useful measures before, or together with, paracentesis We doubt whether Southey's tubes are the best means of withdrawing the fluid from the legs It would have been better if more attention had been paid in the index to subject matter and less to names of authorities, thus we find no reference under "dropsy' to the treatment of this condition, all the pages mentioned dealing solely with its pathology, whereas we find 13 references to Sir William Broadbent, although few readers are likely to want to look up all the passages in which any one author s name is mentioned Still the blemishes are, on the whole, slight and the merits of the book are many We can safely recommend it to students and practitioners as a useful handbook

THE treatises on physiology which are at the disposal of the student may be divided though without any strict lines of demarcation into three classes At one extreme stand the primers of Foster Lowne, Starling, Beale and Ashby, which aim only at supplying the reader, professional or otherwise, with a general view of the subject, yet often contain a considerable amount of very serviceable information the acquisition of which by the learner would prevent the exhibition of total ignorance of particular subjects that is sometimes displayed at examinations by men who are in other points well informed At the other extreme are the large and comprehensive works on physiology the publication of which was initiated by Haller at the close of the eighteenth century and which were followed by the "Handworterbuch der *Physiologie*" *of Wagner, by the Todd s* "*Cyclo*pædia of Anatomy and Physiology," and by the treatises of Schäfer, Howell, and the later editions of the works of Foster in English of Landois in German, of Morat and Doyon and of the "Dictionnaire de Physiologie " in French, which last, beginning in 1895 has only now reached the letter G at the end of the sixth volume, promising to run on for at least another decade These comprise the whole field of physiological research, usually give bibliographical references, and supply such information that for further research the original memoirs in each subject must be consulted Between these extremes are a number of text-books, manuals, elements, handbooks, and essentials of physiology, like those of Yeo, Halliburton Starling, Anderson Stewart, Noel Paton, Raymond, M'Kendrick, *Ott, Hall, and* Waller in

English; Ranke, Valentin, Grünhagen, and Borvttaw in German; and Beaunis and Kuss and Duval in French; all of these aim at supplying the medical student with a succinct account of the present state of our knowledge of the functions of the body which can be understood without the reader possessing much acquaintance with physics, mechanics, chemistry, mathematics, or other collateral sciences. Such treatises usually represent the basis or groundwork of the lectures delivered by each professor, which he expands and illustrates in his discourses by freehand drawings on the blackboard, by larger and more elaborate drawings, by photographic slides and lantern, and by appropriate experiments.

As the foundations of physiology are now securely laid and are given in all these works the superiority of one treatise over another depends on the particular facts selected and the mode in which the story is told or the style in which these facts are presented to the reader. The treatise of Dr. Brubaker belongs to the last-named class and is a favourable specimen of it. The facts are clearly stated, the proportionate space given to each section is reasonable, the student is not troubled with a diversity of opinions, whilst a dogmatic style is adopted throughout. If any faults are to be mentioned one would be that the very excellently executed illustrations are too anatomical. We will take the heart as an example. Dalton's diagrams of the action of the valves really show their function perfectly well, whilst the interior of the heart as shown in the drawings after Allen Thomson are, or ought to be, known to every student during his first year of dissection. In the same way several of the illustrations of the cranial nerves after Hirschfeld and one or two of those in the section on Respiration and Phonation might have been omitted. We are quite aware that an argument in favour of their retention may be maintained on the ground that such illustrations brighten the text and attract the attention of the student and interest him in it. Still, they take up much space and are of doubtful value. Very few students, we imagine, read the lettering of such illustrations completely through. Another defect, and we say this without in any way disparaging Dr. Brubaker's treatise, is that considering that the work is intended for students who are about to become family physicians the application of physiological facts is to a large extent neglected: for example, the effects of cooking on food of various kinds and the advantages of using cooked food are scarcely ever referred to, though Liebig thought it worth while to introduce that subject in a physiological work and the changes effected by cooking probably take an important place in the longevity of man as compared with other primates. It should be pointed out again that the quality of the food ingested is of great importance. We do not suggest a cookery book, but surely a few economic references are not beneath the dignity of the science of physiology. The same observations apply to exercise and athletics and also to the value of the coagulability of the blood, of the retraction of arteries and of the closure of their mouths, and of the failure of the heart's action in syncope from hæmorrhage.

The general arrangement of Dr. Brubaker's work is that several chapters deal with the composition of the body, the physiology of the cell, the histology of the epithelial and connective tissues, and the physiology of the skeleton. The author then devotes two long chapters to the physiology of muscle and nerve and follows these with chapters on the several functions of the body, as food and digestion, absorption, the blood, the circulation, respiration, animal heat, secretion, excretion, the central nervous system, the special senses, and reproduction, all given with much clearness and accuracy. A short section is devoted to physiological apparatus.

We have no space to quote at any length from the text but it may be noticed that Dr. Brubaker gives some interesting calculations in regard both to the superficial area of the blood corpuscles collectively and the rapidity of their reproduction after hæmorrhage. Thus by multiplying the estimated area of a single corpuscle by the aggregate of corpuscles in a cubic millimetre and the number so obtained by the cubic centimetres of blood in the body, which he takes at 5769 grammes or 5463 cubic centimetres, he finds the total area of corpuscular surface to be 3496 square metres—a very large surface to present to the air for respiratory exchange between oxygen and carbon dioxide. Again, the rapidity of reproduction is extraordinary. A computation made by Mr. Charles L. Mix shows that a woman loses during a menstrual period 150 cubic centimetres of blood. At the end of 28 or 30 days this volume is restored, so that in one day five cubic centimetres or 5000 cubic millimetres of blood must be formed, or 208 cubic millimetres per hour and three and a half cubic millimetres per minute. In other words, during a certain number of years 15,750,000 corpuscles must be formed in women every minute and this independently of the daily loss due to functional activity. It should be remembered, however, that Dr. John S. Haldane and Professor J. Lorrain Smith consider that the ordinary estimate of the total quantity of blood in the system at one-thirteenth of the weight of the body is far too high and that from one-eighteenth to one-twentieth would be nearer the mark. Dr. Brubaker overcomes the difficulty of explaining the nature of extravascular coagulation of blood by briefly, as well as lucidly, stating the five different theories of Schmidt, Hammarsten, Arthus and Pagés, Pekelharing, and Lilienfeld, though we should have been glad to find some hint of his own views to guide the student.

The get-up of the work is extremely good and beyond a few typographical mistakes in the spelling, especially of foreign names, we have not discovered any errors.

Under the Care of the Japanese War Office. By ETHEL McCAUL, R.R.C. With illustrations from photographs. London, Paris, New York, and Melbourne: Cassell and Co., Limited. 1904. Pp. 256. Price 6*s*.

Miss McCaul's book will, we think, be perused with both profit and interest, and certainly with a considerable degree of the latter, on the part of the general reader. To begin with, it relates to the war in the Far East, to which all eyes have been turned since the commencement of the struggle between Russia and Japan for supremacy in that part of the world; and it gives some brief sketches of the personalities of many Japanese generals and other authorities with whom Miss McCaul came in contact in the course of her mission and with whose names and deeds the reading public have of late become so familiar. The book is in diary form and is necessarily discursive, but it is written in a fresh and easy style which, so far as the Japanese arrangements are concerned, becomes highly eulogistic. The fact that Miss McCaul had had previous war experience in South Africa, having nursed in a field hospital with Sir Redvers Buller's column from the battle of Colenso to the relief of Ladysmith, qualified her to bring an educated and intelligent judgment to bear upon all that she saw and heard and to take advantage of the facilities so freely afforded to her by the Japanese Government and War Office for studying the systems of military nursing and hospital arrangements in their actual working order. Miss McCaul, it may be remarked, undertook her special mission to Japan and Manchuria in order to obtain information about the Red Cross Society and military nursing at the seat of war. This was done with the sanction of Queen Alexandra and this book relating the results of her experiences is dedicated to Her Majesty. Miss McCaul was received in audience by the Empress of Japan and was everywhere treated with all courtesy and consideration. All nursing and hospital arrangements were freely exhibited for her inspection and she also proceeded to the front, visiting the battlefield at the Yalu. One of our reasons for stating all this is to call attention to the very different consideration and treatment accorded to our medical attaché, Colonel W. G. Macpherson, R.A.M.C. This officer, whose previous training and knowledge of both our own and of continental army systems rendered him well qualified to appreciate at their right value Japanese methods of procedure, seems to have been meanwhile losing the opportunity of doing so owing to the supine action of our own War Office. The lady diarist tells us that finding him still regretfully waiting at Tokio on her return there from the front she handed him a valuable translated paper on sanitation and some photographs on the understanding that he should use them in his own official report.

There is no department of the army that is subjected to more severe and, we may add, often very unfair criticism than the army medical service for its alleged shortcomings in the field. It is consequently mortifying to find this lady nurse saying, "It is very grievous to think how little real trouble is taken at home by the officials to see that our army medical men do actually acquire the priceless knowledge and experience which are to be gained only at the commencement of a war like the present." And to quote again, "The authorities at home seem to content themselves with the fact that an army doctor has been sent out to Japan, but as to seeing whether he has the suitable means for carrying out his mission is a secondary consideration."

Speaking of the favourable impressions which she derived from all that she was privileged to see Miss McCaul says that these far surpassed her expectations. The Japanese, as we all know, are an extremely clever people endowed with extraordinary powers of organisation and stimulated by a patriotic ardour which is almost carried to fanaticism. Amongst their most distinguishing traits are economy and exactness—"an *economy* without stint, and an *exactness* which involves the minutest attention to the smallest of details." Indeed, it may be said that as the whole civilised world now recognises the fact that there is no longer any need to dwell upon the remarkable qualities which the Japanese army have exhibited in this war, so it may be also said that these qualities are equally manifest in the medical branch of it. In the way of excellent organisation, singleness of aim and purpose in its methods of procedure, and strenuous efforts in practically accomplishing the work which it has set itself to do, the Japanese medical service has admittedly done uncommonly well in the present war. Nor need we go far to seek the explanatory cause of this success—namely, its preparedness for war. Every detail had been carefully thought out and practically provided for in order to give the Japanese soldier a complete equipment and field outfit readily adaptable to the varied conditions that he might have to encounter in the field; and as regards the organisation and administration of the hospital service and sick transport from front to base every arrangement which foresight could suggest seems to have been well considered and, where deemed advisable, adopted. It is in respect of these details that the value of Miss McCaul's book with its illustrations mainly consists and makes it worthy of being studied. It embodies as much as could well be included within the limit of its pages and quite sufficient to make it both profitable and interesting reading. This only serves to make us share in the regret expressed by the author that the earliest opportunity of seeing and fully reporting on matters of such importance and interest to the army and its medical service was, *owing to no fault of his*, lost to the medical attaché who was sent out by the War Office for this express purpose.

LIBRARY TABLE.

Five Years' Medical Work on Lake Nyasa. By ROBERT HOWARD, M.B., B.Ch. Oxon. London: The Universities Mission to Central Africa. 1904. Pp. 105. Price 2*s.* 6*d.* net.—This little book is practically a report made by Dr. Howard to his medical board, Dr. Howard being a member of the Universities Mission to Central Africa. It is now published by order of the general committee. The report contains a variety of information which will be found of great use to every worker in Central Africa and indeed in many other regions of the same continent. On p. 9 we find an excellent note on precautions against mosquitoes but we think that the description of the mosquito net should be made more clear in a future edition. After laying stress upon the fact that mosquito nets are usually too small Dr. Howard says: "They should be seven feet long, three feet wide, with calico round the lower two feet of the net." We read these instructions over and over again without being able to understand them in the least and we have a fairly wide experience of mosquitoes and nets. Finally, we wrote to the secretary who kindly forwarded us a pattern which made the matter quite clear but he also forwarded us a copy of instructions for making the net which were even more incomprehensible than those given by Dr. Howard. In a future edition this passage should either be altered or else deleted, for as it stands it is useless. The net as completed is seven feet wide, seven feet high, and three feet broad, and obviously if kept in good condition is a complete protection. The calico all round the bottom is indispensable. Dr. Howard also points out that the bed should be large enough to allow the sleeper to be covered by the net without coming into contact with the net, a point which is often overlooked. The remainder of the book is mainly taken up with medical reports of the various stations and the general conclusion to be drawn from the report is that firstly it is foolish for European missionaries to try to live like natives; secondly, that the rule that a new comer should have a furlough at the end of his first two years has been very beneficial; and thirdly, that there is need for a hill station as a holiday and recruiting establishment.

Herbert Fry's Royal Guide to the London Charities. London: Chatto and Windus. 1905. Pp. lvi.-387. Price 1*s.* 6*d.*—The 1905 edition of this valuable compilation is as full and useful as ever. Mr. John Lane, the editor, contributes an interesting preface in which he says: "The past year has been a bad one, not only for all hospitals and charitable institutions, but for trade generally." Let us now consider what a vast sum of money London takes for charities in a bad year. According to the Classified Directory to the Metropolitan Charities for 1905 there was given a sum in charity, excluding the money subscribed for foreign missions, of, in round figures, £5,500,000. If to this be added the sums given out of the rates to education, relief in sickness and relief in poverty, the average man cannot but wonder why there should be such exceptional distress as is existent at the present time in Tottenham and West Ham. All the same, the charitable will, we hope, continue to give and for him who wishes to know how to give alms wisely there is no better small guide than the one now before us.

The Englishwoman's Year-book, 1905. Edited by EMILY JANES. London: Adam and Charles Black. Pp. 358.—This excellent book of reference now published for the twenty-fifth year fully sets forth the vast sphere of work of various kinds which is now open to women. Education, the professions, industrial work, the arts, public work, philanthropic, social, and religious work, are all dealt with and apparently the lonely and unemployed spinster of former years should now be a thing of the past.

THE LANCET.

LONDON: SATURDAY, JANUARY 21, 1905.

The Report of the Medical Officer of Health of the Administrative County of London.

WE are indebted to the clerk to the Council for a copy of Sir SHIRLEY F. MURPHY'S report on the health of the Administrative County of London for the year 1903. As the volume has been in our hands for only a few hours it is impossible on the present occasion to do more than to notice very generally a few of the chief considerations that are suggested by a first and cursory reading. In later issues of THE LANCET we hope to do fuller justice to a work the production of which must have entailed a vast expenditure of statistical labour on the part of its author and his staff, lay as well as medical. The present report is the twelfth that in the course of his official career Sir SHIRLEY MURPHY has contributed to the literature of preventive medicine. The same general features characterise the arrangement of the entire series but, when the later numbers are compared with the earlier, we are impressed by the steady but very substantial progress, both statistical and administrative, that is revealed in the successive volumes. In his first report the county medical officer had to content himself with a survey of the official reports of the metropolitan vestries and with such statistical data concerning mortality and its causes as could be gleaned from the blue-books of Somerset House. As years have progressed, however, his hands have been strengthened in many ways, notably by the acquisition of powers for the compulsory notification of infectious disease and by the passing of by-laws for the regulation of the building of dwelling houses and for the control of lodging houses.

Again, we are glad to note that only very recently the County Council has completely reorganised the public health department at Spring-gardens and has done so after a fashion that seems calculated to increase greatly its efficiency and to coördinate the action of the several departments which hitherto appear to have worked on practically independent lines. Without going into minute detail we may state that it has been decided to place the administrative charge of the Council's public health and educational departments in the hands of two medical officers who will be responsible to Sir SHIRLEY MURPHY as their chief. According to this rearrangement, which has already received the Council's sanction, Dr. W. H. HAMER assumes the control of one branch with the title of medical officer for general purposes and with the rank of senior assistant to the medical officer of health, whilst Dr. J. KERR continues at the head of the other branch with the title of medical officer for purposes of education. In regard to Dr. KERR, until recently medical officer of the School Board for London, the Council recognises the fact that an important branch of his duty consists in examining into, and reporting upon, the sources and causes of dissemination of epidemic and infectious diseases within the county. It is therefore considered appropriate that this very important work should be brought into the closest touch with the general health administration of London without losing its distinctive characters. This change of system will, in the Council's judgment, be most satisfactorily carried into effect by placing the late School Board's medical officer in the Council's public health department as medical officer (education), an arrangement which will give Dr. KERR a position under Sir SHIRLEY MURPHY who will doubtless allow him a considerable amount of independent action so far as education work is concerned. Accordingly, the arrangement here indicated is now in force and we doubt not that great advantage will in consequence accrue both to the purely sanitary and to the educational work of the County Council. So far as we know the hygienic inspection and control of the metropolitan water-supply have not as yet been vested either in the County Council or, indeed, in any other authority. Nevertheless, having regard to the intimate relationship which is well known to exist between the drinking of contaminated water and the spread of infectious disease, it is obviously desirable that the fullest control should be intrusted to those public authorities who are legally responsible for the maintenance of the public health. Whether or not this change for the better will be accomplished in the near future remains to be seen but it is to be hoped that when the constitution of the new water board comes to be settled the London County Council, the interests of which are so largely at stake, will take care that this aspect of the question shall receive the consideration which it deserves.

From a professional standpoint the most instructive portion of the county medical officer's present report is that which deals with the prevalence and the intensity of disease. In a manner peculiarly his own, Sir SHIRLEY MURPHY martials his facts concerning incidence and mortality so as to indicate clearly the influence thereon of age, sex, and locality, and further, to show how far these have been modified by sanitary surroundings or by meteorological conditions. These details, accurately recorded and uniformly tabulated in the successive reports, have become increasingly serviceable as the years have passed; but at the present time, after a dozen years' experience of compulsory notification, Sir SHIRLEY MURPHY is able to furnish a series of diagrams and tables illustrative of the prevalence and the fatality of the chief diseases in a vast and typical urban community that are not only intensely interesting to the medical practitioner but are almost essential to the local medical officer of health who possesses in these volumes a trustworthy standard to which the rates of attack or of mortality of any prevalent disease in another urban district may fairly be expected to approximate. In his present report the county medical officer of health records a rate of mortality from all causes which in the history of the metropolis is unique. And although in view of the fact that extra-metropolitan England has fully partaken of the general reduction in the death-rate Sir *SHIRLEY MURPHY attributes this very largely* to the persistence throughout the year of unusually favourable meteorological conditions, nevertheless we must not lose sight of the further fact that in the present state of the law London has to accept the unenviable position of an asylum for the accommodation of the refuse alien population from every country in the world. Having regard more especially to the latter consideration we congratulate the county medical officer on the encouraging account contained in his report for the year 1903. In future issues of THE LANCET we purpose to follow in detail Sir SHIRLEY MURPHY'S record of the incidence and the fatality of the several epidemic and infectious diseases dealt with in the volume before us.

◆

Some Thoughts upon Charitable Relief.

To many thoughtful people it is obvious that in the administration of charitable relief there is too often a lack of guiding principles, of economic knowledge, and of cohesion in administration. On this difficult subject a recent volume by the Rev. CLEMENT F. ROGERS[1] throws much clear light. It is a thoughtful and philosophical attempt to formulate lines of action for all almoners, whether clerical or lay, and if the Christian teaching laid down is so much in evidence as to make the work almost theological its good sense brings it within our purview as a paper dealing necessarily with all social problems. We cannot follow the author very far in his attempt to trace the motives of charity to the words of the Founder of the Christian religion. To send a cheque in answer to the first appeal opened and to consign the others to the waste-paper basket is a form of haphazard mercy which assuredly does little to bless either him that gives or him that takes, and while it is opposed to all Gospel teaching it is equally opposed to the most elementary principles of prudence or generosity. No charity worth doing can be done without trouble. The trouble taken is worth more than the gifts given, both to the donor and the social fabric, which includes the recipient. Busy, capable men can often give as much by assisting in administration as by guaranteeing donations. King WENCESLAUS may no longer trudge through the snow with a basket-bearing page but the foremost persons of the realm can (and do), as working members of the practical committees, set most valuable examples in methods of economical expenditure and selection of charitable objective. It is a good omen for our country, we think, that there was never a time when so many great men, busy men, and rich men—men with calls of the most immediate importance upon their time and their talents—were ready to respond to the paramount claims of charity and to help by personal service.

The proper administration of temporary help to those in temporary distress is one of the most difficult tasks in citizenship. It demands a wide scope of knowledge of the conditions of many social grades, a grasp of the economical vicissitude of many forms of labour, the proper estimate of many psychological and physical infirmities, and a discernment, kindly in standpoint, of the influence of inherited taints. The practical almoner must know the value of money in his area of work, the ruling wages of various callings, the prices of necessaries, and, above all, the intricacies of rent. He must know the difficulties of the applicant and the reasons of those difficulties, and the applicant's character, surroundings, work, and power. This knowledge connotes some—nay, a close—grasp of social and economical questions, often too deficient in the average district visitor, and not always abundant in the clergy who are the principal superintendents of the country's alms. To ascertain such points as we indicate care, patience, time, and thought must be lavishly employed. An objection is often made that people who are doing charitable work thoroughly are making a lot of fuss to give away a few shillings. The idea is dominant that "giving away" is in itself good. It would be good if the donor himself conducted the distribution carefully, or even if the gift deprived him consciously of any luxury, but these conditions are rarely fulfilled and facile open-handedness is actually a drawback to the community. In many cases those in temporary distress are as much in need of originality of effort and moral power to reconstruct their lives as they are of material alms but to supply such intellectual help is far more difficult than signing orders for coals or groceries. A worker in poor districts who has no power to refuse the undeserving, no desire to avoid being deceived, and who cannot suffer gladly the infinite capacity for tiresome and ignorant worrying which exists in the distressed poor had better seek some field of occupation more contemplative and philosophical than practical charity; and there is no class in the kingdom knows this better than the medical man who is brought into such intimate relation with the sick poor. A proper estimate of the standards of life and character among the poor is a necessity and can only be acquired by trained experience. The ethical codes of the extremes of society differ somewhat. A virile violence is permitted by society in Plumstead which would be an offence in Piccadilly; in certain industrial quarters lapses from chastity before marriage are condoned which in wives would be severely reprobated—a reversal of Mayfair morals according to modern playwrights and novelists; and, speaking generally, codes vary with material almost as much as with meteorological environment. The charitable worker must learn to appreciate such varieties and to make allowance for them, while maintaining a breadth of mind which will avoid hasty generalisation and preserve him from too rigid classifications. The necessary breadth of idea and duly balanced estimate of conditions can be expected only in persons possessed of education and cultivation; they are not to be found, or rarely, among the poor themselves. That the labouring classes are clumsy and short-sighted as administrators of alms is becoming apparent in the committees of the rural parish councils, though most admirable work is performed by the same class of individuals when working under the disciplined organisation of such bodies as the Salvation Army or Church Army. In the complexities of life of large towns, involving separated areas of dwellings for rich and poor, the personal contact between classes has largely failed. To supply its place a far more carefully devised system of organisation in relief is demanded than was necessary in the village. Personal intimacy and individual help have degenerated into dealing out tickets to a miscellaneous crowd and writing

Annotations.

"Ne quid nimis."

IS ALCOHOL A FOOD?

IN our issue of Oct. 22nd, 1904, p. 1162, we published a leading article under the above heading. We have now received a letter from Mrs. Mary H. Hunt, National Director of the Bureau of Scientific Temperance Investigation, Boston, Massachusetts, in which occurs the following sentence:—"You there assert, as evidence of unwise and tyrannical power wielded by the temperance people in America, that 'school teachers throughout the country were compelled to devote a certain amount of time to instructing their pupils on the dangers of alcohol and were compelled to use only such books as denied that it had any virtues as well.' Your statement shows that you have been misinformed." Mrs. Hunt proceeds to say that it is true that every State in the United States now requires that the nature and effects of alcoholic drinks as a part of physiology and hygiene shall be taught to pupils in all public schools, but there is no law in America that specifies what the nature of alcohol is, nor is there any statute in America that requires only such text-books shall be used as deny that it (alcohol) has any virtue. The laws have left the choice of text-books to the school officials, but, she continues, "For the guidance of these officials a standard as to what is true and what should be taught on this subject was prepared in 1887 by eminent scholars, educators, physicians, members of state boards of health, chemists, &c., but this standard, while influential, had no legal power. It was only advisory." With regard to this statement we reply as follows. Many of the laws in the United States actually specify that one-fifth of the space in the text-books shall be given to "temperance matter" and although they do not legislate as to the character of that matter we can hardly suppose that even moderate praise of alcohol would be reckoned to be "temperance matter." As a matter of fact, though there may not be actual legislation on the subject of the selection of books, the way in which the law operates is such that there is as much compulsion in the use of certain books as though the law had actually specified them. In a further portion of her letter Mrs. Hunt says: "Evidently you have been misinformed concerning the attitude of American temperance reformers for the purpose of being used in a desperate attempt to check the most efficient instrumentality now in operation for the prevention of intemperance. For your recent utterances on this question are being sent out through the newspapers all over the country. In many of these you are being credited with opinions quite contrary to that we have quoted above from your editorial." It is practically not within our power to prevent the press of this or of any other country from publishing garbled extracts from our columns. Mrs. Hunt further implies that we have been exploited for the purpose of being used to check the prevention of intemperance. The simple reason for the publication of the leading article in question was the appearance in the same issue of THE LANCET of an article by Dr. W. H. Goddard—an article which represented some ten years' work and which was a report of a careful physiological investigation into the action of ethyl alcohol as a food. We still maintain that alcohol is a food when used in moderation. It does undergo combustion in the body and it serves as a source of energy. It would certainly be cheaper to get the same energy from the grain or the fruit from which the alcohol was made, but nevertheless it has a food value in the narrow sense in which we were careful to use the word.

YAWNING.

YAWNING is a complex, automatic, physiological phenomenon whereby the lungs are fully expanded, the heart is stimulated to greater activity, and, probably, the blood is charged more fully with oxygen. It commences with an involuntary spasm of certain of the muscles of mastication and deglutition; its termination is akin to the process of sighing, and, like this manifestion of deep breathing, it reinforces respiration. At night, when respiration is slackening, or in the morning, when it has not recovered its waking rhythm, yawning is accompanied sometimes by the "stretching" of successive groups of muscles the blood vessels of which have probably been compressed by the previous assumption of a constrained position; the local circulation is thus assisted and stimulated. The preacher, the novelist, and the artist employ the mechanism of yawning as an indication of ennui, of lack of interest, or of wearied attention, whether real or feigned. To the clinician it should be significant of an attack of asystole and consequent temporary anæmia of the brain, especially of the corpus striatum. In diseases where "air-hunger" is a frequent symptom yawning is also exhibited. It is met with in diabetes, in fatty and fibroid changes in the walls of the heart, in pericarditis, and in the pathological conditions which lead to the faulty filling of the aorta. Yawning suggests the proximity of a fatal ending after copious hæmorrhage and in pernicious anæmia and Addison's disease. Dr. Hughlings Jackson recorded a remarkable demonstration shortly after the introduction of the use of the ophthalmoscope. He was surveying the fundus of an eye when suddenly the field became pale. This pallor was due obviously to a contraction of the retinal blood vessels. He thereupon stood back, expecting something to happen, and in fact the patient immediately yawned. The observer had seen, in part, a spasm of the cerebral arteries.

HOT-WATER STANDPIPES: A SUGGESTION.

IF it could be practicable to supplement gas, electricity, and water-supplies with a public service of hot water it would be an immense boon to householders in London. A constant service of hot water would confer enormous benefits on the community. To mention a few, coal fires could be done away with in domestic buildings and a powerful contributory factor to the formation of irritating and dirty fog would be removed. Standpipes could be erected in the streets and a spray of hot water turned on to remove snow or to render the slippery, icy streets comfortable for the poor hard-working horses. The scenes occasioned in our busy thoroughfares by the sudden onset of a keen gale, severe frost, and pelting sleet on Monday last were of a most distressing kind. Vehicular traffic was perforce suspended and the lot of the horse was of the most cruel description, while pedestrians ran great risk of a nasty accident on the exceedingly slippery pavement. It would be interesting to know how many horses had to be slaughtered owing to the casualties of Monday night. Such abnormal conditions of weather, however, are on the whole happily rare and our street authorities can hardly be blamed for their unpreparedness to deal with the sudden effects of keen frost, wind, and snow upon the roadways and pavements. Indeed, they possess practically no machinery for the purpose. Sand was of very little use; cinders were much more effectual but the supply of small cinders is not easy to obtain. Though the scheme of a general public supply of hot water may appear to be impracticable at present it is not surely entirely chimerical to suggest that here and there in our streets small rapid gas heaters or geysers could be attached to standpipes connected with the water mains. The water, however, need not be intensely hot for the purpose.

The removal of snow or ice by hot water would at any rate be much more satisfactory and comfortable than by distributing salt which produces a nasty intensely cold liquid slush dangerous to the health of both man and beast alike. We commend the suggestion to the members of the Metropolitan Water Board who might lend their aid towards the consummation of such a scheme.

THE DEVELOPMENT OF FLAGELLATED ORGANISMS FROM THE SPLEEN.

IN the November part of the *Quarterly Journal of Microscopical Science* for 1904 Captain Leonard Rogers, I.M.S., the acting professor of pathology in the Calcutta Medical College, gives an account of the development of the flagellated organisms, extremely like those named trypanosomes, which he observed to take place from the protozoic parasites obtained from the spleen in cachexial fevers and in kala-azar. These results were embodied in a paper which we published in our columns on Jan. 7th by Captain Rogers and Mr. G. C. Chatterjee. Kala-azar Captain Rogers considers to be a severe form of the disease formerly termed malarial cachexia, for which he substitutes the term cachexial fever, remarking that this affection is certainly second to none in the frequency and seriousness of the illness which it produces in many parts of India, whilst it also appears to be widely distributed in other countries. The article is accompanied by a plate showing all the intermediate stages from the amœboid stage, corresponding closely with the forms of trypanosoma Brucei described by Rose Bradford and Plimmer in the lungs of animals affected with tsetse fly, to a stage 96 hours subsequently in culture experiments, when the flagellum is fully developed. The drawings were executed by a native artist, Behari Lal Das, and under a $\frac{1}{12}$ lens and a No. 4 ocular the enlargement was 925 diameters. The preparations were all made with Romanowsky's stain used by Leishman's method. The blood was obtained by puncturing the spleen and was immediately placed in small sterilised test tubes containing a little sodium citrate to prevent coagulation, and was then incubated at various temperatures. At blood heat the parasites rapidly underwent degenerative changes and after 24 hours most of them had disappeared and the remainder stained badly. When the culture tubes were placed in a cold incubator at 27° C. (81° F.) the life of the parasites was preserved, their numbers underwent great increase and divisional forms were met with in large numbers, and their characters were studied. Two forms could be distinguished, the first being a simple sub-division of the small oval parasites into two, both the macro- and the micro-nucleus first dividing and then the body of the cell splitting into two longitudinally. Such varieties are rare in blood obtained from spleen punctures but are common in culture specimens. In the second mode of division the process is multiple, both the macro- and the micro-nucleus dividing frequently instead of only once until an appearance is presented of numerous very small nuclei arranged in pairs of a small and a large kind inclosed in a zoogloea-like material. These enlarge gradually, each pair becoming surrounded by a faintly discernible capsule which becomes more and more distinct until the characteristic groups of the oval binucleated fully grown spleen parasites result. These are to be seen in blood obtained by spleen punctures. On lowering the temperature of the citrated culture tubes to 22° C. (72° F.) further and more important changes were soon found. During the first 24 hours the small oval spleen parasites enlarged, the enlargement being chiefly caused by the swelling of the macro-nucleus and of the protoplasm of the cell, whilst the micro-nucleus underwent little change. At the end of 48 hours further enlargement had occurred and double forms appeared which, from various circumstances, led Captain Rogers to regard them, not as the results of division, but as a kind of conjugation analogous to that occurring in other protozoa preparatory to the evolution of new stages in their life-history. At the end of the third day the conjugating pairs of organisms have become elongated and pyriform, the macro-nuclei occupying the thick ends and the micro-nuclei the thinner ends, from which the flagella will eventually arise and in some specimens the flagella had actually been developed. During the fourth day the number of flagellated organisms as well as of double pyriform bodies had greatly increased. Hence it appeared that organisms could be obtained from the spleens of patients suffering from cachexial fevers which in their form, structure, and development closely resemble trypanosomata. A further point of interest is that the fever is endemic, infecting particular houses, and may thus be carried from one to another in the same house by flies or mosquitoes.

FLANNELETTE.

SURELY the days of inflammable flannelette should be speedily numbered. The death roll amongst children who have been fatally injured by the ignition of this perilous fabric is simply appalling. The wearing of flannelette has again and again exposed children to the same risk as if their nightdresses were soaked in spirit. The fabric catches fire as easily and burns with the same intense flame as alcohol, and the flames are not readily extinguished. "An inquest was held yesterday on the body of a little boy, aged two. He was left to play in a room while his mother was absent. He was in a flannelette night shirt. The mother had not left the room long when she heard screams and found the boy in flames. He was terribly burnt and the poor little fellow died within 24 hours of the occurrence." Such is the sort of heartrending paragraph constantly appearing in the newspapers. We are assured that the Home Office has requested coroners to make returns on the number of these cases and surely there is enough sad evidence already to hand to warrant the prohibition of inflammable flannelette for wearing purposes and especially for irresponsible little children One coroner alone has stated that last year he held no less than 73 inquests on children who had been burnt to death and a large proportion was due to flannelette igniting. Are not the sacrifices already sufficient and sad enough to justify the Home Office at once taking very definite action? In this matter what humane person can speak of waiting "until the returns are completed"?

X RAYS FROM STATIC MACHINES.

IN the November number of the *Archives of Electrology and Radiology*, Chicago, is an editorial article entitled "Are the X Rays generated by the Static Machine Dangerous?" The article in question was prompted by a remark which was made by Dr. W. Salisbury Sharpe in a communication to THE LANCET,[1] in which it is stated "that dermatitis from x rays generated by a static machine has not yet been seen." The editor feels that the evil consequences which would result to many if the inference as to safety implied by this assertion were allowed to go without comment justify him in calling attention to the matter. He goes on to say that this opinion as to the innocuousness of static machine-generated x rays was very prevalent up to about four years ago. It was entertained by himself until an unfortunate demonstration of the fact on his own person persuaded him that his trust was misplaced. He instances the cases of two medical men who were severe sufferers from this cause—one of whom had to submit to the amputation of one hand and some fingers of the other. The second case was even more serious, necessitating a severe operation after a long period of complete disability and confinement to bed for several months. While the x rays so generated are not as active in bringing about a dermatitis as are the rays from a tube excited by a coil, yet such rays can, and will, produce burns that are just as bad as those chargeable to the coil-excited apparatus if proper precautions are not taken. In view of the fact that the static machine is very extensively used for x ray work in America, as compared with this country, these remarks must carry considerable weight. That the rays from a tube excited by a static machine possess much less tendency to burn has been common knowledge among x ray workers but it has always seemed to us dangerous to assume that such rays are devoid of any such power. As a matter of fact, dermatitis has been produced in London by means of a tube excited with a static machine. It thus follows that those who practise radiography with a static machine should be none the less careful in their precautions against the production of undesired dermatitis than when using a coil.

---

[1] THE LANCET, Oct. 1st, 1904, p. 958.

THE MEDICAL DEPARTMENT OF TRINIDAD AND TOBAGO.

Mr. Hugh Clifford, Colonial Secretary of Trinidad and Tobago, in his report on the Blue-book of the colony for 1903–04, remarks that the total cost of the medical department for the year under review amounted to £81,233, of which £34,912 were expended on personal emoluments and £46,321 on other charges. This sum, which shows an increase of £6300 over the expenditure under the same heading in the preceding year, is equal to one-tenth of the total expenditure of the colony, and it not only exhibits a tendency annually to increase, but advances automatically with the growth of population of the colony, in a fashion which, under the existing system, defies control. In Trinidad not only has the Government taken upon itself to provide the services of qualified medical officers in districts where the practice available is insufficient to remunerate adequately a private practitioner but it has also assumed as part of its duty the support of a variety of institutions which in Europe are usually maintained either solely or principally by voluntary contributions. The conditions which prevail in this colony are, of course, widely different from those which obtain in most European countries. The number of the very wealthy is here far smaller in proportion to the population; the average of poverty is greater, though indigence in the tropics is robbed of many of the terrors which it has in colder climates; and there is lacking in Trinidad that strong well-to-do middle class which, both in France and in England, forms the backbone of the nation. The few really rich men in Trinidad have innumerable calls upon their generosity; the less wealthy have little to spare when the demands made by the high cost of living have been satisfied; the poorer classes, from whom the principal users of the Government institutions are naturally drawn, are unwilling to pay for what they receive there, even when they can do so although at the cost of some personal inconvenience. The reason for this is partly that the system under which natives of India are introduced into Trinidad necessitates the establishment of estate hospitals and the appointment of medical officers in the districts which immigrants inhabit. The other labouring and the poorer classes, not unnaturally, consider that they have an equal right with the imported East Indian to the privileges and advantages which, in this respect, the latter enjoys; and they are not, therefore, prepared to pay, if payment can be evaded, for what they regard as no more than their due. Beyond this, however, it has seemingly become a fixed idea in the popular mind that the Government is able to provide all that is desired by the individual at the charges of the State without injury to the [illegible] Government property, [illegible] of which each taxpaye [illegible] the opportunity serves [illegible] this can be done with [illegible] for useful expenditur [illegible] impaired. Mindful of [illegible] tropical country, the p [illegible] importance, the Government has found itself obliged to maintain, practically single-h [illegible] for the treatment of the sic [illegible] the diseased, and in so doin [illegible] the support of that sound [illegible] force those who are able to pay to decline to [illegible] the charity of the State whenever [illegible] possibly irksome, is within their [illegible] position is fast becoming serious is [illegible] fact that though the annual expenditure of the department, including the cost of medical and charitable institutions, amounts to one-tenth of the total annual expenditure of the colony—that is to say, to over £81,000 reimbursements derived from paying patients, including members of the police force and others from whose pay deductions are made for the purpose, do not average £3000 per annum. During the year under review 13,493 were admitted to the various Government [illegible] were discharged relieved or cured, and the deaths numbered 1524. The number of patients in the other [illegible] institutions on March 31st, 1904, was as follows: [illegible] asylum, 610; leper asylum, 313; and house of refuge, St. Clair, 371. The total num [illegible] hospitals and institutions on [illegible] little more than 0·7 per cent. [illegible] colony.

IODOFORM FILLING FOR BONE CAVITIES.

THE success attending the ordinary operation of filling stopping carious teeth has doubtless suggested to surgeons the desirability of employing some similar substance for filling the cavities left in bones after [illegible] When the cavity is aseptic, as after the removal of a cyst, it apparently fills with blood clot which organises and so cavity is obliterated but when a bony cavity is septic the process is very tedious for the discharge of pus generally continues for months. About five years ago Professor von Mosetig Moorhof of Vienna commenced to study question of the best method of filling bone cavities. At first he employed an iodoform paste of the consistence of putty but this did not reach the minute recesses of the cavity and therefore he devised a liquid filling of which he gave an account last year in the *Deutsche Zeitschrift für Chirurgie*, and we publish in this number of THE LANCET (p. 146) a description of Professor Moorhof's method and results by Mr. B. Seymour Jones. The filling lately [illegible] consists of iodoform, spermaceti, and oil of [illegible] melts at 122° F. (50° C.), so that when melted it can poured into the cavity and fills it completely. It [illegible] found necessary that the cavity should be aseptic and dry; these essentials are obtained by methods very [illegible] to those employed in filling carious teeth and if [illegible] filling is properly applied only slight serous [illegible] occurs. For the mode of introduction of the [illegible] and the precautions taken we refer the reader to the article mentioned but here we will consider the results. Since iodoform gives a dark shadow in a skiagram it is easy to follow the course of events in the bone cavity. [illegible] dark area is [illegible] showing that the plu [illegible] laced by granulation t [illegible] bsorption that no symp [illegible] turn granulation tissue is replaced by bone, as shown by an extension of a dark shadow from the periphery in the skiagram. Professor Moorhof has now applied this method in some 220 cases. All forms of bone cavity have been filled, whether due to the removal of sequestra or to cysts, and he has even applied it in two cases to an empyema of the antrum of Highmore. He has extended the method to the treatment of joints after excision and in the article referred to details are given of the mode in which it is carried out. It is apparently not essential that the iodoform plugging should be completely covered in, for in a few cases a sinus has communicated with the mouth and yet the process of healing has continued undisturbed. The most remarkable of all the cases was one in which Professor Moorhof operated for two sinuses of the sternum in a girl, 14 years old. Part of the bone was removed and then it was found that there was much caseous material in the anterior mediastinum; when this had been cleared it was discovered that a sinus passed into the posterior mediastinum. When the whole cavity was cleared and cleaned it was filled with iodoform plugging and more than 200 grammes (about seven ounces) were employed. The patient was much improved and the hectic temperature disappeared but death occurred about four weeks after the operation. Professor Moorhof claims to have had no failure in all the cases which he has treated by this method and it certainly deserves a trial in suitable patients. It may have applications in addition to those for which Professor Moorhof has employed it. We shall hope to hear further of this ingenious device and we have no doubt that many surgeons in this country will be willing to put the method to the test of experience.

BUTTER FRAUDS.

BUTTER still appears to be the vehicle of considerable fraud and the margin of profit which the practice yields has led to the devising of some ingenious methods of carrying it on in the teeth of the Margarine Acts. There is undoubtedly a good deal of margarine sold in this country as butter; shops are opened, as appears in the following instances, for the sale of "butter" which, in fact, is margarine, and as soon as a summons is issued the establishment ceases to exist, only to be started elsewhere. Again, when a conviction is obtained the fines are readily paid and every effort is made to prevent a second or third conviction (which brings a large penalty) by changing the salesman in the shop. We referred to this kind of swindle in THE LANCET of Sept. 24th, 1904, p. 906, and the present cases appear to be a sequel. A company of men has been for some few years working on these lines in most of the Lancashire towns by opening shops in Oldham, Bolton, Ramsbottom, Wigan, Blackburn, and elsewhere with the apparent purpose of selling Irish butter from their own farms. Three men were charged with obtaining by false pretences certain small sums of money. It was shown that the prisoners opened a shop in Ramsbottom in November last, sold what purported to be butter to a number of customers at about 10*d.* a pound, and also gave away certain quantities on opening the shop. Such butter according to the description would have been worth 1*s.* 2*d.* per pound. The police purchased certain samples which on analysis proved to be margarine worth 5*d.* or 5½*d.* per pound. The analyst stated that the samples were almost entirely margarine of an inferior quality. The usual defence was put in, one man pleading that he had nothing to do with any false pretence and the others that they did not know what they were selling as they were employed by a third party who paid to them a weekly wage. They were, however, found guilty. The police stated that another man who had been associated with them had been fined £40 for a similar offence and had undergone three months' imprisonment in default. It was stated that there was a gang of about 40 men who opened shops as the prisoners had done and who disappeared when summonses were issued. They were wanted in various parts of the country. The police had a list of between 30 and 40 places where shops had been opened and had been in existence for some time. The chairman said that the bench thought that the prisoners were part of a gang trying to swindle the public, and the poorest of the public. They would, however, for some little time at least, be prevented from doing this. They would be sentenced each to 12 months' imprisonment with hard labour. A few more prosecutions of this nature will do more than the Margarine Acts to prevent the sale of margarine for butter. The officers of the Lancashire county council deserve every credit for running these swindlers to earth and we should like to see similarly successful operations started against many other forms of swindles in which the substitution of the spurious article for the genuine is the rule. Imprisonment with hard labour is more likely to have a deterring effect than the infliction of paltry fines.

LESIONS OF THE OPTIC NERVE FROM FALLS.

THE case of fracture of the anterior fossa of the skull diagnosed as division of the optic nerve by Dr. F. J. Hathaway, recorded on p. 158, presents several points of interest and although the literature of such cases is limited it is not quite so scanty as Dr. Hathaway believes. Thus von Holder gives in an early volume of Graefe and Sämisch's *Archiv fur Ophthalmologie* (Band vi.) the statistics of 124 cases of fracture of the skull, of which 86 were fractures of the base, and in 79 of these the fracture involved the roof of the orbit. In 63 of these cases there was a fissure or fracture running through the optic foramen, always through its upper wall and sometimes also through the inner wall. In 42 cases there was hæmorrhage into the sheath of the nerve, but in all these cases the bony canal was fractured. Messrs. Norris and Oliver in their valuable "System of Diseases of the Eye," from whom we have borrowed the above statistics, state that Dr. Callan has reported nine cases of injury to the orbital walls resulting in immediate unilateral blindness, in which it was believed that the line of fracture ran through the optic foramen. Dr. Callan calls attention to the fact that the frontal bone unites with the nasal, superior maxillary, lacrymal, and ethmoid bones by a continuous line of sutures until the lesser wing of the sphenoid is reached and at this point the suture line bifurcates, forming an obtuse angle and close to the apex of this angle lies the optic foramen. The jar caused by a blow upon the orbit would find its weak point along this line of sutures and the first point of resistance would be at the bifurcation adjacent to the optic foramen. The jar could not follow both lines with equal force at, and beyond, the bifurcation and consequently the unequal strain would result in fracture of the bone in the optic foramen, causing compression or laceration of the optic nerve. Dr. Noyes, who in his "Treatise on Diseases of the Eyes" gives some excellent and instructive drawings, states that Prescott Hewett gathered together 68 cases of fracture of the base and found that the orbit was involved in 23. Panas, again, calls attention to the fact that according to Leber and Deutschmann fractures of the roof of the orbit implicate the orbital canal in 60 per cent. of all cases. Dr. Hathaway seems to have no hesitation in stating that the optic nerve was divided in his case but there is little doubt that hæmorrhage into and outside the sheath of the nerve in its course through the optic canal has been observed on post-mortem examination and the symptoms point to this. A rider, for example, is thrown from his cycle and falls heavily on his shoulder, striking the side of his head. On recovering from the shock, and before swelling begins, he finds that he can see. As the ecchymosis of the lids proceeds he is unable to open the lids and has temporarily complete loss of vision. When the swelling has subsided vision is again recovered to some extent and may then in course of years again slowly deteriorate with supervention of white atrophy, or it may remain stationary with much impairment, or it may undergo some improvement; in the latter case probably hæmorrhage in the orbital canal took place at the time of the accident and the effused blood has undergone partial absorption. Only a necropsy can determine whether the nerve is actually divided. It is only surprising that amongst the innumerable falls which cyclists have suffered more instances of this kind have not been recorded. Probably many cases have occurred but the visual trouble is lost sight of or disregarded in view of the cerebral and often fatal lesion.

THE CASE OF DR. A. D. GRIFFITHS.

As will be seen by a letter which appears in another column, Dr. A. D. Griffiths's local professional brethren have not confined themselves merely to passing resolutions of sympathy with him in the terrible anxiety which he has recently undergone. The facts of the case were duly set forth in an annotation published in our issue of Dec. 17th, 1904, p. 1733, under the heading "A Vile Conspiracy." Shortly to recapitulate them they were as follows. A woman named Faithfull asked Dr. Griffiths to attend her for some gynæcological trouble. At the second attendance the husband assaulted Dr. Griffiths, at the same time heaping accusations upon him. The wife also swore in court to acts of immorality with Dr. Griffiths but as the result of an action brought by him for slander the jury awarded to Dr. Griffiths £500 damages. The judge pointed out that in his opinion Faithfull's charges were absolutely groundless. The defendant did not appear and of course the £500 will never be paid. Dr. Griffiths has been saddled with expenses to the amount of some £205 and the medical men of Cardiff and the neighbourhood have accordingly determined to raise a fund whereby to reimburse him. We have the greatest pleasure in giving voice to their appeal for funds and we trust that not only the medical men of South Wales will subscribe but also many of those in other parts of the kingdom. Such an experience as Dr. Griffiths has recently undergone may be equally the lot of any practitioner in the kingdom and the courage with which Dr. Griffiths faced a very painful situation not only has worked for his own good but for that of every one of his professional brethren.

ADMINISTRATION OF WATER BEFORE GIVING CHLOROFORM TO PREVENT VOMITING.

In the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of Dec. 25th, 1904, Professor Denucé has described a simple method of preventing vomiting after administration of chloroform which he has found very successful—the administration of water before the anæsthetic is given. The *rationale* of the method is as follows. During the induction of anæsthesia acts of deglutition may be observed. These result in the swallowing of air charged with chloroform. The chloroform irritates the mucous membrane of the stomach, which according to the usual practice is empty, and causes vomiting. Hence the efficacy of lavage of the stomach which has been employed in the treatment of the vomiting. Professor Denucé therefore asks, Why not prevent the vomiting by not allowing the chloroform vapour to come in contact with the mucous membrane of the stomach? This can be accomplished if the chloroform vapour enters a stomach full of fluid instead of an empty one. Fluids are withheld before the administration of chloroform from fear of vomiting and the passage of the vomited matter into the air passages. But it is well known that most troublesome vomiting may occur with an empty stomach and the vomiting of a small quantity of water would not be attended with much danger. Moreover, as suggested, the presence of chloroform in an empty stomach is probably the most frequent cause of the vomiting. In attempting to prevent this result by insuring the presence of fluid in the stomach it must be remembered that liquids may be quickly absorbed from the stomach or pass into the intestine. After several trials Professor Denucé adopted the following method. One and a half hours before the operation the patient is given a "large glass" of water and the dose is repeated every half hour until the time of operation when the last one is taken. Thus in all four "glasses" are taken amounting to about 800 grammes of water. The results exceeded Professor Denucé's expectations. In 20 cases *there was not the slightest vomiting or even nausea during* or after the operation. Many of the operations, which included laparotomy for double ovariotomy, radical cure of inguinal hernia, and operation for hydatid cyst of the liver, were long and complicated. That 20 cases are insufficient to decide the merit of any method all will admit but independently of the small number of cases recorded there seems reason to doubt Professor Denucé's premisses. The probable cause of sickness after chloroform inhalation is not so much the swallowing of the vapour of chloroform as the ingestion of saliva and mucus impregnated with the vapour in the mouth. Salivation is provoked by most of the anæsthetics in use and when it is excessive vomiting is severe but the nausea and emesis are reduced or prevented when care is taken to prevent the patient swallowing. The lateral posture of the head will usually effect this. In patients who have gastric trouble tenacious mucus is liable to collect in the viscus and if this is brought in contact with swallowed chloroform which has become condensed the vomiting may persist for days. It is in such cases that lavage, whether complete or only practised as Professor Denucé recommends, proves most useful. It washes away this thick glairy mucus and prevents the chloroform remaining as an irritant to the mucous membrane of the alimentary tract.

AN UNJUST RIDER.

At Lewisham last week Dr. H. R. Oswald, the coroner for the South-East district of London, held an inquest upon a commercial traveller who had died two days previously from small-pox. The coroner stated that the deceased was sent to the Metropolitan Asylums Board receiving station at Rotherhithe, it being thought by three local medical men that he was suffering from small-pox, and that when he arrived at Rotherhithe he was seen by the superintendent who decided that the case was not one of small-pox and sent him home again, where he died. Evidence was given in support of this statement and Dr. T. F. Ricketts, medical superintendent of the small-pox hospitals of the Metropolitan Asylums Board, owned frankly that death had probably been due to hæmorrhagic small-pox. Whereupon the coroner's jury having brought in a verdict in accordance with the medical evidence, added an unjustifiable and ill-informed rider. This was to the effect that when a case was sent to the Rotherhithe receiving station a certificate should be forwarded, signed by two medical men, stating that they were *of opinion that the person was suffering from small-pox*, and also that the case should not be rejected unless it was seen by another medical man in addition to the superintendent.

For some 12 years Dr Ricketts has been engaged in the task of receiving or rejecting small pox patients and this is the first occasion upon which the grave difficulties of diagnosis seem to have betrayed him Such a record of successful observation has seldom, if ever, been achieved, for it implies being correct in many thousands of instances as against one slip small pox being notoriously one of the most difficult diseases to diagnose The idea that medical certificates from outside could be employed to remove discretion from the superintendent of the small-pox hospitals is silly, as silly as is the suggestion that the superintendent should be provided with a consultant physician We hope that the Metropolitan Asylums Board will take some steps towards a public display of confidence in Dr Ricketts whose record is such a good one and whose splendid work in the last epidemic of small pox, work of one man as it was, counted a great deal in the safety of a community of millions We think that if the coroner had realised the situation he would have pointed out to the jury the mistakes in their rider

THE SUPRARENAL CAPSULES

A LONG and carefully written report on the development structure, and functions of the suprarenal capsules by Dr R Minervini of Genoa appears in the September and October numbers of the *Journal de l'Anatomie* Dr Minervini prefixes a short historical notice to his essay in which he states that the capsules were discovered and described in 1563 by Barthélmy Eustachius, or at least mentioned by him in his work entitled "De Renibus Libellum,' published in that year They were subsequently described by Bauhin and by Casserius who named them "renes succenturiati and by Bartholinus by whom they were designated "capsules atrobiliaires," believing them to secrete a humour called "atrobile" Little advance was made till the middle of the last century when Addison demonstrated their connexion with bronzed skin Since Addison's time much attention has been paid to them in consequence of the remarkable action of their secretion in producing increase of blood pressure, demonstrated by Ed Schäfer, and Dr Minervini has examined the development of the capsules in a very large number of vertebrates from fish upwards but has specially devoted his attention to birds and mammals We can only give here a *résumé* of the results which he has obtained In regard to birds he finds that *in the embryo of the hen's egg* the first indication of the capsules is on the fourth day of incubation and in that of the pigeon on the third day In both an isolated cellular nodule makes its appearance in the mesoderm behind the peritoneal epithelium and close to the root of the mesentery It is upon a level with or a little above, the upper end of the Wolffian body and the germinal epithelium and is prolonged towards the lower and internal part of the Wolffian body and dorsally to the germinal epithelium These three parts—Wolffian body, germinal epithelium, and suprarenal capsule—may therefore be considered as developing simultaneously but the capsules form independently of the other two Hence the hypothesis of its connexion with the pronephros as others have noticed in the amphibia seems to be highly probable In regard to mammals and man it may be said that during embryonic and fœtal life the suprarenal bodies are in general of large size in comparison to that they attain to after birth In the human fœtus they are always larger than the kidneys Each capsule is composed of a single substance—that is to say, of special cells which present but slight differences in point of size amongst themselves either in the central or in the peripheral regions But Dr Minervini is not in a position to say whether these cells form the cortical substance of the capsule alone, so that there is no medullary portion during the whole of embryonic life, or whether, as seems to him most probable, they represent both the cortical and medullary portions of the capsules not yet differentiated or in an almost indifferent state, the distinction into cortical and medullary portions occurring at a later period He has never met with true nerve cells in the capsules but has frequently found vascular glomeruli—a fact that has not hitherto been mentioned in regard to mammals, though such bodies were seen by Rabl in the fowl They occupy a position in the external and middle zone and seem to atrophy as the time of delivery approaches The capsules appear at a very early period of embryonic life in the dog and in man but do not then present any relation with the Wolffian body or with the cortical gland substance The structure of the suprarenal capsules is given by Dr Minervini in much detail not adapted for abstraction and is illustrated by four plates and many figures As regards the functions he considers that notwithstanding that they contain lymphatic tissue and nervous elements they are essentially glands and that the cells of the medullary substance are not nervous but glandular and probably less advanced in evolution than those of the cortical portion The capsules contain two substances, both of them toxic and both possessing the power of raising the blood pressure They are glands producing an internal secretion (endocrines) and like other glands with an internal secretion their action is complex and manifold Besides regulating the composition of the blood and exerting a more obscure influence on the genesis or destruction of pigment they undoubtedly possess an *antitoxic action—that is to say, they* neutralise various poisons of endogenous origin derived from organic metabolism, especially that or those proceeding from the disintegration of muscle They also exert a regulating action on the circulation of the blood owing to their hypertonic and angeiotonic properties It may even be admitted that they have an antitoxic action on bacterial poisons, fixing or neutralising them in a mode of which we are at present ignorant and in this way they play a part in defending or protecting the system from infections Lastly, it may be said that they influence the sexual functions, or at least that the function of the capsules is in relation with those of the sexual organs, responding, so to speak to the phases of sexual life

CHRONIC PEMPHIGUS OF THE MOUTH

IN some cases of pemphigus mucous membranes, especially that of the mouth, are attacked In rare cases mucous membranes alone are affected and the disease may not be diagnosed In the *Boston Medical and Surgical Journal* of Dec 22nd, 1904, Dr J W Farlow has published two cases of chronic pemphigus of the mouth In one case the patient was a girl aged 22 years, and in good health For nearly a year she had complained of blisters forming in the mouth, *generally* on the gums near the teeth They appeared from time to time and were painful and interfered with eating On the gums near the front teeth and on the inside of the cheek was a whitish membrane easily detached and leaving a raw surface Some of the spots were of the size of a cherry stone, others were larger Examination of the teeth gave no clue to the cause The blisters continued to appear and the patient was lost sight of In the second case a woman aged about 55 years, was seen in July, 1897 For some time blisters had appeared on the lips and gums and the inside of the cheeks On examination slightly raised reddish swellings with raw surfaces were found on the gums near the upper left front teeth In September the inside of the cheek and the under surface of the right side of the tongue were very sore In October blister appeared inside the right lower alveolar process They were at first reddish but soon lost their covering and became raw and tender. In spite of general and local treatment crops of blisters appeared from time to time in the mouth. The patient went to Europe and was treated by several eminent dermatologists without success. In 1904 she had ulceration of the right cornea and lost the sight of the eye. She was treated in New York during about a year for pemphigus of the conjunctivæ and mouth. The blisters in the mouth were controlled by arsenic which she had difficulty in taking. Blisters also occurred on the mucous membrane of the nose, chiefly on the septum, with pain, formation of crusts, and obstruction to the breathing. At one time the vagina was affected. In the treatment of pemphigus of the mucous membranes it is most important to keep the teeth, mouth, nose, and throat clean by the use of alkaline and antiseptic washes in order to prevent secondary infection of the erosions. If the pain interferes with eating it may be necessary to use local anæsthetics such as cocaine, orthoform, or morphine. Internal treatment is not satisfactory, though arsenic is strongly advocated by some writers.

CURRENT THEORIES OF THE HEREDITARY PROCESS.

IN the second lecture[1] delivered at University College, London, on Nov. 29th, 1904, Professor W. F. R. Weldon dealt with the phenomena of reproduction as it occurs in the sea-urchin (*Echinus*), an organism higher in the scale of development than Hydra. The egg of Echinus is surrounded by a relatively thick gelatinous envelope, at the top of which exists a pore (micropyle) for the entry of the spermatozoon, whereby the fertilisation of the egg is effected. The nucleus of the egg cell is situated in the upper region of the cell. The lower part of the ovum is coloured by a pigment band in the region between the equator and the lower pole of the egg. "This pigment band," said Professor Weldon, "is a landmark which enables us to follow with facility the cleavage and division of the ovum after impregnation." The impregnated nucleus divides into two parts, the cell protoplasm undergoing a similar division, the divided nuclear and cellular portions seeming to be equal in size and similar in appearance. The first and second cleavages take place in the vertical plane and at right angles to one another, thus giving rise to four blastomeres, each provided with its band of pigment in the proper position. The volume of the four blastomeres is equal to that of the parent egg cell; there has been cell division without growth of bulk. An equatorial division now occurs of the blastomeres resulting in an eight-cell stage. The four upper cells are slightly tinged with pigment at their lower poles; the four lower cells contain practically all the pigment. From the four pigmented cells are budded off four smaller "micronuclear" cells which occupy the lower pole of the mass of blastomeres, while the four upper pole cells divide into eight. This mass of 16 cells is termed the morula. The eight clear cells of the upper region give rise to the ectoderm of the future embryo or larva, the eight pigmented cells of the lower zone give rise to the alimentary canal (archenteron), cœlomic epithelial walls, and gonads, while the unpigmented micronuclear cells creep inwards during the next stage of growth and give rise to the mesamœboid cells. The next stage (blastula) is characterised by further cell division and the formation of a hollow sac the wall of which is wholly composed of "clear" and "pigmented" cells, the micronuclear cells having proliferated and migrated within. These mesamœboids subsequently give rise to the right and left mesoblastic masses or bands arranged on each side of the gut which is now being invaginated from the lower pole of the blastocœle. There is at first radial symmetry but as the process of invagination (gastrulation) advances bilateral symmetry succeeds; a bending of the gastrula and gut takes place so that a ventral and dorsal aspect is recognisable. On the ventral side is formed the stomodæum or mouth, by a local depression of the ectoderm meeting and fusing with the blind end of the gut. A band of perioral ectoderm with cilia now develops and two long bifurcate calcareous spicules are formed within the body. The ciliated band becomes prolonged into two oral and two anal processes, and the stage of a free-swimming larva (Pluteus) is attained. Driesch has found that a blastomere of the two-cell or four-cell stage if isolated is capable of forming a half-sized or miniature but perfect gastrula and larva, and that even a blastomere of the eight-cell stage develops into blastula, gastrula, and larva. Moreover, pieces of moderate size cut from the globular blastula before invagination has begun grow up and close into small blastulæ which produce perfect larvæ. But after invagination has taken place pieces cut from the organism do not produce perfect larvæ but defective or monstrous forms which die. The equipotential stage of the cells in the blastular cell wall has gone. Certain constituents in the sea water are, said Professor Weldon, necessary for the proper development of Echinus; thus if calcium salts are absent abnormal morula and blastulæ appear and the same occurs at high temperatures, above 28° C. The future functions of cells essentially equipotential are largely determined by their position in the blastula, the experiments and studies of Driesch, Hertwig, Morgan, and Roux showing that this holds good for echinoderms, nemertine worms, amphioxus, the tunicates, teleostean fishes, and amphibia, while by partial mechanical separation of blastomeres in the pre-embryo of the frog double-headed, double-tailed, and other monsters can be produced (Hertwig, Speman, and Born). On the other hand, the egg of Nereis (Wilson) and of Beroë (a ctenophore) shows high degrees of preformation, and the early blastomeres of the two- and four-celled stage are not equipotential. The significance of these facts in heredity and disease would be pointed out later.

MUNICIPAL ECONOMY AND THE STANDARDISATION OF DISINFECTANTS.

WE understand that the public health committee of the Chelsea borough council has decided to modify the schedule for the supply of carbolic disinfectants so that the price shall be based upon the germicidal equivalent of the preparation and not on its volume. In the case, for example, of a tender requiring 2000 gallons of carbolic acid or its germicidal equivalent 200 gallons of any disinfectant having a guaranteed carbolic acid coefficient of over ten would represent the same germicidal efficiency, and if the prices quoted were 1*s*. 6*d*. per gallon in the former case and 4*s*. in the latter there would obviously be a considerable saving. This is a step in the right direction, for the real value of a disinfectant is, after all, its germicidal efficiency, just as the value of certain commodities is dependent upon the proportion of active principles which they contain. Thus the price of chloride of lime used for bleaching purposes is based upon its proportion of active chlorine and the price of a fertiliser upon the percentage of principles (phosphates, nitrates, or ammonia) available for the sustenance of plant life.

THE annual dinner of the present and past students of the University of Durham College of Medicine, Newcastle-on-Tyne, will be held in the library of the College on Friday, Feb. 3rd, at 7.15 P.M. Dr. R. S. Peart will be in the chair. Tickets, 7*s*. 6*d*. each, may be obtained on application to Mr. A. Beresford Jones or Mr. Sydney

---

[1] An abstract of the first lecture appeared in THE LANCET of Jan. 7th, p. 42.

Havelock, honorary secretaries at the College Students and graduates of other universities will be welcomed

---

THE annual dinner of the West London Medico Chirurgical Society will take place at the Wharncliffe Rooms, Great Central Hotel, on Wednesday, Feb 8th, at 7 o'clock Communications should be addressed to Dr A Elliot, 11, Upper Berkeley street London, W.

THE fourth meeting of the Bristol Medico Chirurgical Society was held in the Medical Library, University College, Bristol, on Jan 11th, when Professor T. Clifford Allbutt delivered an address to a full meeting of members and visitors on the Prevention of Apoplexy

---

A TELEGRAM from the Governor of the Mauritius received at the Colonial Office on Jan 13th states that for the week ending Jan 12th there were 8 deaths notified from plague

---

His Majesty the King has accepted a copy of Mr F J Gant's "Autobiography" which has just been published

Looking Back.

FROM

THE LANCET, *SATURDAY*, Jan. 20, 1827.

During the Peninsula war, the superior anatomical, and of course chirurgical, knowledge of those army surgeons educated in Dublin soon attracted the notice of the distinguished individual placed at the head of the Army Medical Establishment, and with a conscientious and honest discharge of the high trust reposed in him, he advanced those men in rank and responsibility, upon whose professional knowledge, when so much was at stake, most reliance could be placed, no matter what was their previous patronage country, or religion Those alone were selected who were most capable of affording the best chance of life or limb to the wounded soldier, and in consequence, numbers of our countrymen, educated in this city, and filling subordinate situations in the army were advanced with rapidity to posts of responsibility, rank, and emolument This naturally opened the eyes of many to the superior advantages afforded by Dublin for the acquisition of surgical and anatomical knowledge, and we have had consequently, since the war a number of pupils from England and Scotland, annually resorting to our schools, which I shall venture to predict will every year increase

Unfortunately, our own foolish ordinations have interfered to mar the progress of Dublin as a school of anatomy and surgery It is natural, and a matter of course, that pupils should wish to receive their diplomas of qualification from those constituted bodies under which they have been educated and from the hands of those professors and seniors who have observed the progress that each has made in the acquisition of medical and surgical knowledge

This very natural [illegible] baffled by the Charter of [illegible] which enacts that no per[illegible]ination who has not served an apprenticeship to a regularly educated surgeon, and this is the *only test* of qualification demanded from the pupil by this corporation charter *No* attendance upon lectures *no* attendance upon hospitals *no* dissections, are required by the framers of this wise sample of legislation, and in fact, at this very moment, in point of law the President and Examiners are bound to examine any man, no matter whether he has ever been inside the walls of an hospital or lecture room—if he has only served an apprenticeship to what is designated a regularly educated surgeon, he may demand an examination

But the framers of the Charter forgot in their wisdom to define what are the qualifications which render a man a regularly educated surgeon Their successors, I presume, taking it for granted that the only qualification to make a regularly educated surgeon is an apprenticeship to one, demanded from every pupil who had not been an apprentice to a Licentiate or member of the College of Surgeons in Ireland, sufficient documentary evidence that his master not only had been a regularly educated surgeon, but that he had also served *his* time to a regularly educated surgeon, and thus I have known the time of the Court of Examiners occupied, day after day, examining the genealogy of a candidate, even to his professional *great great grandfather*![1]

THE ARMY MEDICAL SERVICE OF GREECE.

BY F HOWARD, M D ST AND,
COLONEL, ARMY MEDICAL STAFF (RETIRED)

GREECE although one of the smaller States, has a well-organised Army Medical Service The normal army in 1896 consisted of 24 877 officers and men but all able bodied males, aged 21 years and upwards, are liable to serve The army in 1903 consisted of 1876 officers, 4670 non commissioned officers and 15 795 men[2] The regulations for the Greek Army Medical Service deal with a variety of matters connected with *personnel*, hospitals, distribution of sick, provisions for chemical analysis and micro biological researches, supply, nursing, &c There is a special health department under the Ministry of War which deals with the organisation and mobilisation of both the sanitary and veterinary services the supply of *matériel* for ambulances medicines and surgical instruments, and the management of health establishments with their *personnel*

Military Hospitals—These are of the first and second class according to the strength of the corps which garrison the town In 1902 the military hospitals of Athens, Larissa, Missolonghi, and Tricala were decreed first class hospitals as each of the three first named was the headquarters of a division of two brigades and the last named was a brigade headquarters Each first class hospital is under the superintendence of a surgeon lieutenant colonel who is the director The higher *personnel* is composed of a surgeon major (sub director) two surgeon captains, one surgeon lieutenant one apothecary with the rank of major, one apothecary ranking with lieutenant, two apothecaries as sub lieutenants and one captain for supply Hospitals of the second class exist in Corfu Arta, Tyrnavos, and Nauplia under a surgeon major who is the director, one surgeon captain (sub director) one surgeon-lieutenant two sub lieutenants one apothecary with the rank of captain, two apothecary sub lieutenants, and one lieutenant for supply

The hospital and infirmary service is performed by military medical officers and apothecaries varying in number according to the importance of the establishment These are assisted by a staff composed of administrative or economical officers civilians, and military of lower grade hospital orderlies and bearers The *personnel* of these hospitals number in all 159 medical officers and apothecaries, many economical officers subordinate employés and two hospital orderly and bearer companies At each divisional hospital there exist a depôt for drugs and surgical instruments and a chemical and bacteriological laboratory There is a medical school at Athens for the fuller instruction of medical officers

Hospital orderly and bearer companies—There exist two [illegible] also [illegible]itary [illegible]y are obliged to pass an examination the successful candidates being drafted into the Hospital Orderly Company and assuming forthwith their duties at the different hospitals and infirmaries, while the unsuccessful pass into the bearer companies

Rank—The highest rank obtainable in the Military Medical Service of Greece is that of medical inspector-general who ranks with a colonel The highest rank obtainable by apothecaries is that of lieutenant colonel, and the highest rank in the Veterinary Service is that of major.

---

[1] [illegible] to a Course of Surgery [illegible] Carmichael president of [illegible]

[2] [illegible] the Hellenic Chamber of [illegible]ich military service for all [illegible]ears of which two will be [illegible]le for an army of from [illegible] The three divisions on the [illegible] six each containing two infantry brigades two battalions of chasseurs à pied one regiment [illegible]ers, with [illegible] infantry [illegible] of from [illegible] is joined [illegible] war the [illegible] The new [illegible]rps and [illegible]

Medical and veterinary services.—The peace establishment is: 2 medical inspector-generals, 7 inspectors (of the rank of surgeon-lieutenant-colonel), 10 surgeon-majors, 34 surgeon-captains, 45 surgeon-lieutenants, 32 surgeon sub-lieutenants, 1 apothecary-in-chief, 3 apothecary majors, 9 apothecary captains, 7 apothecary lieutenants, 9 apothecary sub-lieutenants, 1 veterinary surgeon-in-chief, 8 veterinary captains, 4 veterinary lieutenants, and 4 veterinary sub-lieutenants.

War organisation.—In war time time the Field Sanitary Department is divided into: (*a*) Field surgeons accompanying corps; (*b*) Provisional hospitals to which the patients of the field surgeries or hospitals are transferred. (*c*) Depôts for medical stores. The Central Depôt is at Athens and other depôts are at Volo, Santa Maura, and Piræus. (*d*) The ordinary base hospitals. The field surgeries or hospitals and the provisional hospitals are under the immediate direction of a headquarters medical staff (*archiatrion*) which is again under the orders of the general or colonel commanding the corps.

The following is the constitution of the Headquarters Medical Staff: 1 surgeon-lieutenant-colonel, 1 surgeon-lieutenant, 1 apothecary lieutenant, 1 "economical" (supply) officer, 1 lieutenant for transport of the medical service, 1 assistant surgeon, 1 sergeant, 2 corporals, 1 corporal for transport service, 8 soldiers, and 8 mules. The field surgeries or hospitals are first, second, third, and fourth class according to the number and importance of the corps which they accompany in the field. A fourth-class surgery is capable of accommodating 40 men.

The provisional hospitals.—These are of the first and second class and their *personnel* is, so far as possible, the same as the first- and second-class ordinary divisional hospitals. The accompanying table gives at a glance the *personnel* of the headquarters and first-, second-, third-, and fourth-class surgeries:—

—	Headquarters surgery, 16,000 to 20,000 men.	First-class surgery, 8000 to 16,000 men.	Second-class surgery, 4000 to 8000 men.	Third-class surgery, 2000 to 4000 men.	Fourth-class surgery, 2000 men.

Military infirmaries exist in Ithaca, Santa Maura, Zante, Pitras, Amphissa, Agrinion, Ogina, Colambaku, Carvassara, Carditza, Corinth, Pyrgo, Sparta, Tripoli, Lyra, and other places.

Uniform.—The medical officers have a blue-black tunic with reddish-lilac velvet collar; blue-black trousers; and blue-black cap with lilac velvet band. Non-commissioned officers and men of the hospital orderly and bearer companies are dressed like the infantry with the Geneva cross on the arm. The badges of rank are as for infantry.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Jan. 8th, Mr. JOHN TWEEDY, the President, being in the chair.

Mr. Bernard Pitts was introduced and having made a declaration in the terms of the oath prescribed by the Charter of 1800 he was readmitted a member of the Court of Examiners.

The SECRETARY reported the death on Dec. 19th, 1904, at the age of 49 years, of Mr. A. Quarry Silcock, member of the Court of Examiners. A vote of condolence with the members of his family was passed.

The PRESIDENT stated that the vacancy in the Court of Examiners occasioned by the death of Mr. Silcock and the vacancy caused by the expiration of the period of office of Mr. W. H. A. Jacobson would be filled up at the next ordinary meeting of the Council on Feb. 9th.

It was resolved to refer to the Museum and General Purposes Committee to consider and to report upon the question of permanently installing the electric light in the museum.

A report was read from the President and the Vice-Presidents on the proposed foundation of scholarships in memory of the late Mr. E. Percy P. Macloghlin, M.R.C.S. The report was approved and adopted and it was resolved that the best thanks of the Council should be given to Mrs. Macloghlin for her munificent offer and that she should be informed that the Council gratefully accepts the trust and agrees to administer it upon the conditions mentioned in the report. The amount to be given to the trust of the College is £10,000.

The Council proceeded to discuss the case of a Member who had been removed from the Medical Register by the General Medical Council and after deliberation it was resolved that his name should be removed from the list of Members of the College.

The PRESIDENT reported that on behalf of himself and the Vice-Presidents, in pursuance of the authority given to them by the Council, they had appointed Dr. H. Timbrell Bulstrode to represent the College at the Conference on School Hygiene arranged by the Royal Sanitary Institute to be held in London from Feb. 7th to 10th, 1905.

Mr. Edmund Owen presented to the College on behalf of Mr. Edward Atkinson, M.R.C.S., of Leeds, six saws invented and used by Hey for operations on the skull. Its best thanks were voted by the Council to Mr. Atkinson for his very interesting gift.

A letter was read from the secretary of the Queen Victoria's Jubilee Institute for Nurses reporting the expiration in February next of Mr. T. Bryant's period of office as a member of the council of the institute and inquiring whether Mr. Bryant is to remain the representative of the College on the council of the institute for the next three years. The consideration of the matter was postponed.

A letter was read from the honorary secretaries to the committee for organising the visit of French physicians and surgeons to London expressing the thanks of the executive committee for the cordial reception extended by the President and the Council of the College to the French physicians and surgeons on the occasion of their visit to the College.

A letter was read from the Registrar of the General Medical Council reporting the adoption by that Council of the following resolution, in addition to the eight resolutions in regard to preliminary scientific education and examination adopted at the May session:—

> That the synopsis or syllabus in elementary biology should include as necessary subjects of study the fundamental facts of vegetable and animal structure, life-history, and function, as exemplified by specified

types of cryptogamous plants (including bacteria) or protozoa and of at least four of the higher animal groups, and the outlines of embryology.

Mr. G. H. MAKINS moved:—

'That a committee be appointed to consider and report upon the practicability of the institution by the College of a school for the teaching of the early and intermediate subjects of the medical curriculum and advanced pathology.

The consideration of the matter was postponed.

CHICAGO.

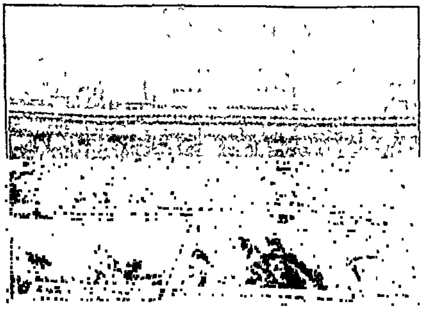
TUBERCULOSIS AMONG THE STOCKYARD WORKERS.—SANITATION IN PACKINGTOWN.—THE POLICE AND THE DUMPING OF REFUSE.—VITAL STATISTICS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Continued from p. 123.)

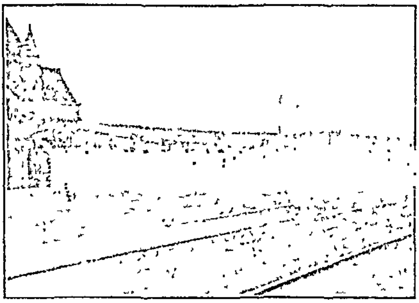
THERE is at Chicago a city committee which has been formed to deal with the question of tuberculosis and to devise measures for combating this disease. As there are more cases of tuberculosis in the Stockyard district than in any other part of Chicago, Dr. Hedger, who is a member of this committee, was appointed to inquire into the matter. Within the district of four miles square, of which one square mile is occupied by the stockyards and the other three square miles are inhabited by the people who work in the stockyards, 200 deaths from tuberculosis had been recorded during a period of two years and five months. Dr. Hedger started on the inquiry expecting to find that there were special streets and special groups of houses where the disease pr [illegible] such an abnormal manner as to show that the [illegible] themselves were absolutely unhealthy and [illegible] Therefore cards were printed, one for every hou[illegible], these cards a systematic record was to be kept. The number of families, of sleeping rooms, and the total number of inhabitants in each house had to be inscribed carefully. But it was soon found that the houses were not in a bad condition. There were isolated cases of overcrowding but it was not general. In other parts of Chicago where tuberculosis is not so prevalent the overcrowding is more general and very much worse. Sometimes there were too many sleeping in one room but the houses were fairly clean. In the whole of the district there is only one house that is four storeys high. The houses are more like cottages and, as already stated and shown by reproductions of photographs, there is plenty of air space around them. There is hardly a house to be found which touches another house though the space between them may at times be only three feet, and this is insufficient when it is sought to obtain through windows light and air from such side passages. Then it was also ascertained that no two deaths from tuberculosis occurred in the same house during the two and a half years of close observation. But on going further back the former history of some of the dwellings showed that there had been several cases in one and the same house; indeed, there was one house in particular which seemed to be infected. Of course, the homes of the stockyard workers are far from perfect. For instance, they are not provided with bathrooms and the supply of public baths is altogether insufficient. Again there is the old grievance that the inhabitants do not ventilate their houses sufficiently. But these are defects which exist in all poor quarters. Neither the houses nor their inmates can be said to be worse than elsewhere. Dr. Hedger, after living amid these people and spending much time in their homes, considers that their chief defect is the unsuitable nature of their food. They are very fond of sweetened bread and coffee, whereas porridge and wholemeal bread would be more likely to prevent the present excessive frequency of anæmia.

FIG. 7.



Bird's-eye view of the cattle pens with cattle-run in the background. View from the chief inspector's office.

FIG. 8.

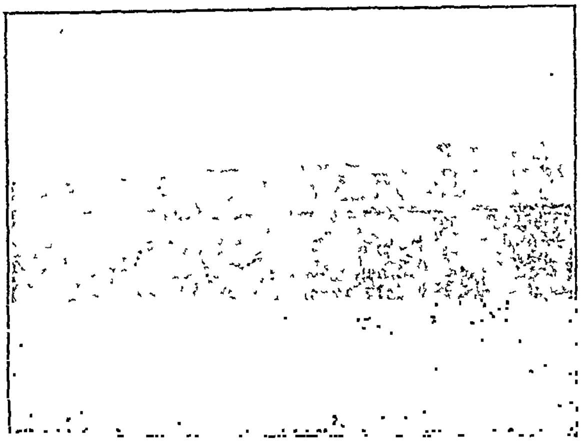


Main entrance to stockyards, showing cattle-run ascending from level of railway line to the second floor of the meat factory.

Of course, when a population grows with great rapidity on a spot which has never been inhabited before it requires emphatic local by-laws and a very energetic sanitary authority to see that proper sewers and an ample water-supply are provided before houses are built. In Packingtown the paving of streets has been very generally neglected and in some districts houses were built before sewers had been constructed. Consequently the inhabitants here and there have suffered from the nuisance inseparable from cesspits. The same objection obtains in most rural districts where, nevertheless, there is the lowest death-rate. The nuisance of a cesspit is amply compensated for by the advantage of living on virgin soil and the fact that the whole of Packingtown is built on soil which had not been inhabited previously must be carefully borne in mind. It explains why the fatal consequences of insanitary conditions have not as [illegible] W[illegible]rse by far [illegible] sewers, is [illegible] Here the [illegible] of filth to accumulate on the surface of the water which is foul in the extreme. Fortunately there are very few habitations in close proximity to this festering nuisance. The land on both sides of the river is vacant and where utilised it is for the purpose of railway traffic and not for habitations. So here again what might be a cause of ill-health does not produce all the mischief which, in other circumstances, would undoubtedly ensue.

Another local grievance is the fact that some old clay brick-fields are now used as a dumping ground for refuse collected, not only in the district but from other and distant quarters of Chicago. This ground and this enterprise belong to a town councillor and therefore it is but natural to expect that the business will be carried out without creating a nuisance. Nevertheless it is difficult to believe that this is actually the case, for a member of the city police is kept to watch the spot and to drive away persons of an inquiring mind, especially if they belong to the press. Perhaps it might be well to raise a question on behalf of the inhabitants of Chicago and to ask whether it is their desire that their money should be employed to pay policemen to prevent the truth from being known in regard to matters concerning the public health. In spite, however, of the policeman a photograph is here reproduced which I took while menaced by the terrors of the law. The dumping is done without any sorting and from open carts. Therefore the dust and lighter articles are blown away for a distance of about a quarter of a mile around. The heavier rubbish is gradually filling up the holes made by digging out the clay which was used in the manufacture of bricks and it is quite evident that houses will ultimately be built on this refuse. If the policeman is there to see that no building is attempted on the top of such a foul accumulation there would be some sense in it. Unfortunately, it is pretty evident that the object of his presence is to prevent the inhabitants of Chicago from knowing how unhealthy and artificial a subsoil is being prepared for their future dwellings. In the meanwhile a considerable part of the dust, rags, and paper is blown about and makes the surrounding fields look quite white. On one side of this large open space and within easy reach of the dust there are a pond from which the ice is taken and sold and a building for the trade in ice.

FIG. 9.



View over the dumping ground of the town refuse. Packingtown and the stockyard chimneys are in the distance. To the left, not distinguishable, is an ice factory.

It is in this neighbourhood also that the houses are not yet connected with the sewers and indeed the whole district looks wild. But few streets have any semblance of pavement. The backs of the houses abut on to bare uneven earth. The cinders and refuse are thrown into dustbins made of a few planks roughly put together so that a good deal escapes and is blown about; fortunately there is plenty of wind and of open space for it to undergo the process of natural purification. Outside the houses there are sorts of terraces made of wooden boards which are sometimes as high as three feet above the street. These serve as causeways where people can walk well above the mire of the unpaved street. In a word this part of the city is not built. Some of the houses have been constructed before the ground was properly laid out and prepared. Still the water-supply is there and in most places there are sewers also. It is this newness which for the time being saves the situation and accounts for the comparatively favourable character of the vital statistics. The very worst part of the whole district does not contain more than 113 inhabitants to the acre and there is only one acre where the population is equal to this. At the commencement of the year 1901 Chicago was mapped out into 15 sanitary divisions. The following is the official description given by the town authorities of the Stockyard district.

> The eleventh division comprises 7120 acres with a population of 252,980, largely of foreign birth. ..... This is the "packing-house" district in which are located the union stockyards, abattoirs, large packing houses, and kindred industries, with the working people employed therein and their families Ground low and only partly drained; long settled in the northern part and of recent development along the south west border. The northern half is bisected by the south fork of the south branch—an open sewer for the highly charged drainage of the industries congregated along its borders. In the longer settled northern part the sanitary conditions are poor, the dwellings old and of cheap construction. These conditions improve to the south where the recent increase of population is better housed.

This description must be taken comparatively, bearing in mind that nothing is really old in Chicago. It shows that the population only amounts to 35 per acre. In the Bowery district of New York, round about Rivington-street, the population is close upon 1000 per acre. In London there are places where about 400 persons are packed on an acre of ground, while in the very worst part of the Stockyard or Packingtown district of Chicago the population does not exceed 113 and the average of the district is only 35 to the acre. This is a fundamental fact and it must be carefully borne in mind. Precisely how far it has affected vital statistics no one can say. In any case there is the corresponding fact that the death-rate is low. The question remains whether in such very favourable circumstances it ought not to be lower still.

The department of health has issued a volume giving many figures relating to the new division of the city into 15 sanitary districts. Here we find the population of Chicago estimated for the year 1901 at 1,758,025 and the death-rate at only 13·88 per 1000. Then the actual number of deaths in the 15 sanitary divisions is given but not the proportional figures. However, in another document issued in February, 1901, the population per division is given, and here it is stated that in the eleventh or Packingtown division the population was 252,980. The number of deaths being 3466, this would be 13·64 per 1000, or a trifle less than the average for the whole city. From the descriptions given it would appear that the fifth, the sixth, and the fifteenth are the most insanitary districts of Chicago. Of the fifth division we are told :—

> It embraces some of the most densely populated and poorest-housed areas in the city. The former sixteenth ward in the northern part of this division had a population of 148 to the acre in 1900 The eighteenth ward is essentially a lodging-house district with a shifting population—crowded in winter, sparse in summer—largely adults without steady occupations. The population of the division as a whole, is mainly of the poorest classes, with a large foreign element and a relatively large child population. The dwellings are old, largely of wooden construction, and usually overcrowded.

The population being set down at 466,052 and the number of deaths at 6962, this is a death-rate of 14·7 per 1000, and indicates that the insanitary conditions described were telling on the population, though if these figures are trustworthy the inhabitants still enjoyed for a large town an exceptionally low death-rate.

Of the sixth division we are told :—

> This is the poorest and most densely populated area of the north side, having a population of 125,875 mainly of foreign birth.

As the number of deaths was 1789 this equals a death-rate of 14·21 per 1000. In regard to the fifteenth district the official description says:—

> The area is chiefly of low ground, poorly drained, and the general sanitary conditions are exceedingly unfavourable. The habitations are principally old wooden structures.

The population was 50,800, the number of deaths 751, or a death-rate of 14·7 per 1000.

Such was the situation in 1901 and it will be seen that what were described as the worst districts had a slightly higher death-rate while Packingtown enjoyed the low death-rate which the abundance of open spaces should confer. In the short space of two years a remarkable change may, however, be noted. Though the board of health takes upon itself to increase its estimate of the population of Chicago to 1,873,880 it will be found that the death-rate has augmented considerably, for instead of 13·88 per 1000 it is now put down at 15·42 per 1000. The increase of deaths is much greater in proportion than that of the population. Unfortunately, I have no estimate as to the distribution in the 15 sanitary divisions of the 115,855 new inhabitants of Chicago The number of deaths per division which occurred in 1903 is given and if calculated on the basis of the population as given in 1901 then the death-rate per 1000 has increased from 14·7 to 17·8 in the fifth division, from 14·21 to 15·98 in the sixth division, and from 14·7 to 15·5 in the fifteenth division. In the eleventh division, the Packingtown district, the increase is from 13·64 to 17·76, and in spite of the figure just given for the fifth division the general opinion or *impression* I found prevalent in Chicago is that the death-rate is higher in Packingtown than in any other part of the city. Unless the population of Packingtown has greatly increased in the two years mentioned this would now seem to be the case; at least, it can be said that the death-rate is as high in Packingtown or the eleventh division as in the fifth division and that in these two districts the death-rate exceeds considerably that of the average for the whole of Chicago. Then there remains this important argument, that if the higher death-rate in the fifth division be explained by reason of insanitary conditions prevailing in that district, the poverty, thriftlessness, and uncertain earnings of its inhabitants, the same argument does not apply to the eleventh division or Packingtown. Dr. Hedger, in dealing with the fact that there were proportionately more cases of tuberculosis in Packingtown than in other parts of Chicago, started with the impression that the homes of the inhabitants would be found in a more insanitary condition than in other parts of the city. A lengthy and minute investigation proved that in other parts of Chicago the overcrowding and the insanitary conditions of the dwellings were much worse. Therefore, if the homes are better and nevertheless the death-rate is higher, then it is the character of the work which does the harm. This, especially in regard to tuberculosis, would not be the first time a similar condition has been discovered. It has been demonstrated on a much larger scale by the comparison of the reduction in the prevalence of tuberculosis in England and in Germany. In England more women and in Germany more men have benefited. The explanation of this difference is simple. In England our improvements have in the main effected the sanitation of private dwellings and this is where most women work and spend their time. In Germany the law enforcing the insurance of all the working classes has led to greater improvements in the sanitation of factories and workshops and has therefore proved of more benefit to men than women. Conditions that favour the spread of tuberculosis also favour many other diseases and in Packingtown these conditions are to be found in the work that the people do rather than in any exceptionally insanitary dwellings. On the contrary, the people are much better housed than is generally the case with that class of worker.

(To be continued.)

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9044 births and 5251 deaths were registered during the week ending Jan. 14th. The annual rate of mortality in these towns, which had been 19·4, 22·4, and 19·9 per 1000 in the three preceding weeks, further declined to 17·5 per 1000 last week. In London the death-rate was 16·8 per 1000, while it averaged 18·3 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 7·6 in Willesden, 8 1 in Hornsey, 8·6 in Hastings, 10·1 in Reading, 10·5 in Leyton, 11·0 in Handsworth (Staffs.), and 11·2 in Walthamstow; while the highest rates were 24·3 in Newport (Mon.), 26·5 in Middlesbrough, 26·7 in Warrington, 27·6 in Swansea, and 35·8 in Stockton-on-Tees. The 5251 deaths in these towns last week included 378 which were referred to the principal infectious diseases, against 399, 475, and 399 in the three preceding weeks; of these 378 deaths, 114 resulted from measles, 86 from whooping-cough, 60 from diphtheria, 42 from scarlet fever, 40 from diarrhœa, 31 from "fever" (principally enteric), and five from small-pox. No death from any of these diseases was registered last week in Hornsey, Hastings, Brighton, Southampton, Ipswich, Handsworth (Staffs.), Smethwick, Aston Manor, Wallasey, Warrington, Rotherham, and Newport (Mon.); while the highest death-rates from the principal infectious diseases were recorded in East Ham, Nottingham, Bury, Middlesbrough, Stockton-on-Tees, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Bristol, Nottingham, Liverpool, Wigan, Stockton-on-Tees, Cardiff, and Merthyr Tydfil; from diphtheria, in East Ham, Northampton, King's Norton, and Stockton-on-Tees; from whooping-cough in Grimsby, Huddersfield, Hull, and South Shields; from "fever" in Bury; and from diarrhœa in Middlesbrough. The mortality from scarlet fever showed no marked excess in any of the large towns. Of the five fatal cases of small-pox registered in these towns last week one belonged to London, one to Oldham, one to Bradford, one to West Hartlepool, and one to South Shields. The number of small-pox cases under treatment in the Metropolitan Asylums hospitals, which had been 14, 17, and 18 at the end of the three preceding weeks, had further risen to 19 at the end of last week; one new case was admitted during the week, against nine, five, and one in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, on Saturday, Jan. 14th, was 2192, against 2394, 2387, and 2308 on the three preceding Saturdays; 194 new cases were admitted during the week, against 242, 201, and 187 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 416, 521, and 443 in the three preceding weeks, further declined last week to 301, and were 107 below the number in the corresponding period of last year. The causes of 61, or 1·2 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Salford, Leeds, Newcastle-on-Tyne, Cardiff, and in 44 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Warrington, Blackburn, Preston, Sheffield, West Hartlepool, Sunderland, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21·2, 21·6, and 20·6 per 1000 in the three preceding weeks, rose again to 21·6 per 1000 during the week ending Jan. 14th, and was 4·1 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·4 in Paisley and 15·6 in Greenock, to 23·9 in Glasgow and 27·7 in Aberdeen. The 723 deaths in these towns included 45 which were referred to whooping-cough, 16 to diarrhœa, 12 to measles, five to diphtheria, four to "fever," and three to scarlet fever. In all, 85 deaths resulted from these principal infectious diseases last week, against 90, 78, and 79 in the three preceding weeks. These 85 deaths were equal to an annual rate of 2·5 per 1000, which was 1·2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 31, 40, and 37 in the three preceding weeks, rose again last week to 45, of which 38 were registered in Glasgow, four in Edinburgh, and two in Perth. The deaths from diarrhœa, which had been 12 and 13 in the two preceding weeks, further rose to 16 last week and included 11 in Glasgow and three in Dundee. The fatal cases of measles, which had been 19, 20, and 14 in the three preceding weeks, further declined last week to 12, of which seven occurred in Aberdeen and four in Glasgow. The deaths from diphtheria, which had been two and four in the two preceding weeks, further rose to five last week, and included two in Glasgow and two in Edinburgh. The fatal cases of "fever," which had been eight, two, and eight in the three preceding weeks, declined again last week to four, all of which were registered

to diseases of the respira-

ch had been 174, 184, and 182 in the three preceding weeks, were 183 last week, and were 15 below the number in the corresponding period of last year. The causes of 21, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·6, 25·0, and 25·6 per 1000 in the three preceding weeks, declined again to 22·6 per 1000 during the week ending Jan. 14th. During the past four weeks the death-rate has averaged 24·4 per 1000, the rates during the same period being 18·2 in London and 18·5 in Edinburgh. The 164 deaths of persons belonging to Dublin registered during the week under notice were 22 below the number in the preceding week, and included 21 which were referred to the principal infectious diseases, against 12, 26, and five in the three preceding weeks; of these, 12 resulted from measles, four from diarrhœa, two from diphtheria, one from scarlet fever, one from whooping-cough and one from "fever." These 21 deaths were equal to an annual rate of 2·9 per 1000, the death-rates last week from the same diseases being 1·0 in London and 1·4 in Edinburgh. The fatal cases of measles, which had been ten, 18, and three in the three preceding weeks, rose again last week to 12. The deaths from diarrhœa which had been one, six, and one in the three preceding weeks, rose again to four last week. The 164 deaths in Dublin last week included 32 of children under one year of age and 44 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a slight decline from the numbers recorded in the preceding week. Six inquest cases and three deaths from violence were recorded; and 65, or nearly two-fifths, of the deaths occurred in public institutions. The causes of 11, or nearly 7 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

The following appointments are notified:—Fleet Surgeons: H. X. Browne to the *Vivid* for Devonport Yard and H. S. R. Sparrow to the *Cambridge*. Staff Surgeons: E. C. Cridland to the *Forte*, on recommissioning; A. E. Kelsey to the *Scylla;* and E. T. Meagher to the *Fire Queen* for the *Hercules*, for voyage to Gibraltar. Surgeons: W. B. Macleod to the *Hermione* for voyage to Ascension and back; G. C. C. Ross to the *Leviathan* and on replacing the *Bacchante;* L. Lindop and F. E. Anley to the *Bacchante* for passage home; G. H. S. Milln to the *Fire Queen* for disposal; E. A. G. Wilkinson to the *Vivid* for disposal; R. Hughes to the *Penguin*, additional, and on recommissioning; H. C. Ross to the *Ganges;* A. F. Fraser to the *Surprise;* E. Folliott to the *Imogene* on recommissioning; G. Ley to the *Flora* on commissioning; N. J. Roche to Plymouth Hospital; F. R. Featherstone to the *Fire Queen* for disposal, lent to the Royal Naval College, Osborne; and E. Cox to the *Pembroke* for disposal.

Royal Army Medical Corps.

Lieutenant H. B. Connell is seconded for service under the Foreign Office (dated Dec. 31st, 1904). Captain C. J. O'Gorman, D.S.O., from the Seconded List, to be Captain (dated Jan. 1st, 1905). Captain P. G. Stock resigns his commission (dated Jan. 14th, 1905).

Volunteer Corps.

Rifle: 5th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Captain T. Wood resigns his commission (dated Jan. 14th, 1905). 3rd (Dundee Highland) Volunteer Battalion the Black Watch (Royal Highlanders): Edward Fox MacLeod Neave to be Surgeon-Lieutenant (dated Jan. 14th, 1905). 2nd Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): The undermentioned Surgeon-Lieutenants to be Surgeon-Captains: H. Allan (dated Jan. 14th, 1905) and J. H. Maclean (dated Jan. 14th, 1905).

Deaths in the Services.

Sir James J. L. Donnet, K.C.B., Inspector-General of Hospitals and Fleets, R.N. (retired), on Jan. 13th, at Bognor, in his eighty-ninth year. He entered the Royal Navy in 1840, became fleet surgeon in 1845, deputy inspector-general in 1867, inspector-general in 1875, and retired in the following year. He was present in the *Vesuvius* at the operations on the coast of Syria and at the siege and fall of the fortress of St. Jean d'Acre, and he had charge of the Hospital at Acre after the fall of that place (war medal, Syria clasp, and Turkish medal). Later he acted as secretary to the diplomatic mission sent by the British Government to the Sultan of Morocco and was in medical charge at the successful capture and destruction of the town of Ngunduvan, in Viti Levu, Fiji. He served in the Arctic Expedition in 1850–51 (*Assistance*) when the first footsteps of Franklin were discovered (Arctic medal) and was senior medical officer of the flagship *President* at the attack of the allied squadrons on the stronghold of Petropaulowski, in Kamschatka, in 1854, and at its dismantling in 1855. He was in administrative and executive charge of Port-Royal Hospital, Jamaica, during the epidemic of yellow fever of 1867 and 1869. He was principal medical officer in charge of medical wards of Royal Naval Hospital, Haslar, during the epidemics of small-pox and enteric fever and cases of fever and dysentery after the Ashantee war in 1873–74, and in administrative and executive charge of Royal Naval Hospital, Malta, in 1874. In 1877 he was appointed a member of the committee appointed to inquire into the causes of the outbreak of scurvy in the Arctic Expedition under the command of Sir George Nares, K.C.B. He was awarded the good service pension in 1878, the Diamond Jubilee medal in 1897, and the Coronation medal in 1902. He was appointed honorary surgeon to Her late Majesty Queen Victoria in 1870 and honorary physician in 1893.

The War in the Far East.

Since writing last week on this subject many events of much moment have taken place although none of them can be said to have any special medical interest. The Czar has issued an order of the day in which he announces the fall of Port Arthur, pays a tribute to Russian valour, and points to the past history of Russia as giving an assurance of the ultimate victory to his Imperial Majesty's troops and fleets. What is the truth about Port Arthur and the circumstances leading up to its surrender are matters which have yet to be determined. According to the statements now put forward the surrender was an inglorious end to the siege. It is alleged not to have been brought about by want of ammunition and scarcity of food or the loss of positions. It seems clear from the accounts which have been published that the physical plight of the Russians in Port Arthur was, after all, far better than that of General Sir George White's army at Ladysmith at the time of its relief. It is stated that the Japanese were told at first that only 4000 unwounded men remained but the number proved to be 24,000, who have been actually shipped to Japan. A large number of them were suffering from scurvy or were very slightly wounded but there was no sign of their having starved. The hospital supplies had, however, failed. It is, meanwhile, very ungenerous to seek to belittle the spirit and the deeds of the Russian garrison until all the facts are better known than is now the case.

As regards the belligerent armies in Manchuria the state of relative inaction still continues. There has, indeed, been a big cavalry raid on the part of the Russians, but it practically led to no results so far as the objects in view were concerned, the Cossack force being repulsed with much loss by the Japanese. There is, if true, some rather ominous news of the failure of the Trans-Siberian railroad to meet all the requirements of the situation in Manchuria and of the increasing difficulty of supplying the material wants of General Kuropatkin's large army.

Correspondence.

"Audi alteram partem."

THE ORGANISMS OF VARIOLA, VACCINIA, AND VARICELLA.

To the Editors of The Lancet.

Sirs,—As several of your correspondents have been discussing the characters of the organisms of variola and vaccinia the following case may interest them. It is interesting as proving that two specific fevers may coexist, that the protective effect of vaccination does not last for eight years, and that it is almost impossible to give an opinion with certainty in mild cases of variola.

I was treating a typical case of scarlet fever at the beginning of the small-pox epidemic here in 1901. Six days after I first saw him (during which time he was isolated) he developed some spots on the legs and the arms which became papular, vesicular, and pustular. I diagnosed variola. The diagnosis was confirmed by three other medical men. On careful cross examination of the boy I found that he had been visited on the second day of his scarlet fever confinement by an old friend who slipped into his room for a few moments unknown to the nurse. This man had been helping to disinfect a house in which several cases of small-pox occurred. The period between exposure and the appearance of the rash was therefore only five days. The boy was eight years of age and had good vaccination marks. There were no constitutional symptoms except a very slight rise of temperature when some of the spots became pustular.

When the scarlet fever appeared I advised the removal of a younger sister to a friend's house at the seaside. This child was about six years of age and had never been vaccinated. I vaccinated her on Oct. 9th, before the brother developed the scarlet fever on the 14th. On the 21st she left for the seaside, with a vaccination scar on her arm. On the 26th the medical officer of health (having been warned to keep his eye on her) saw her and found a number of tiny vesicles with shotty feel on the forearms wrists and legs These faded in a day or two There were no symptoms The child was not exposed to personal contact with the visitor who gave the disease to her brother, having been from home on that day There was not any case traced to her afterwards, although she was only partially isolated The probable explanation is that the spots were a delayed vaccination rash or a mild case of varicella

I am, Sirs, yours faithfully,

THE TREATMENT OF HÆMOPTYSIS

To the Editors of THE LANCET

SIRS —In THE LANCET of August 20th (p 522) and Oct 1st (p 942), 1904, under the head of "The Medical Treatment of Deep seated Hæmorrhage," I contributed a series of eight cases in which 13 attacks of hæmoptysis (12 phthisical and one mitral) had been, with one exception, all stopped within three minutes by inhalation of amyl nitrite In the exception the bleeding continued in reduced amount for ten minutes Since writing the above I have received the following from Dr E Leslie Pooler of South Australia "I have tried the amyl nitrite treatment for pulmonary hæmorrhage with complete success On the night of Sept 27th, at 11 30 P M, I was called for the first time to see Mr A, aged 45 (a tubercle case), who I was told, had been bleeding since 10 P M There was about a pint of blood Inhalation stopped the hæmorrhage almost instantaneously On Sept 28th, 29th 30th, and Oct 1st there were further hæmorrhages but each ceased immediately on the inhalation There has been no further hæmorrhage since Oct 1st"

In THE LANCET of Nov 19th, 1904, p 1406 I gave *a priori* reasons for believing that the internal administration of adrenalin would tend to exaggerate or to prolong hæmoptysis These anticipations seem fully confirmed by the experimental work of Dr T G Brodie and Dr W L Dixon on the "Alterations in the Systemic Circulation which tend to produce Engorgement of the Lung Capillaries, communicated to the Pathological Society of London[1] These investigators point out that there is no evidence that adrenalin produces any constriction of the vessels of the lung, that adrenalin produces engorgement of the lung, and further that ergot and digitalis both act similarly Do not these facts all point to amyl nitrite inhalation as the rational treatment for hæmoptysis?

I am, Sirs, yours faithfully,
FRANCIS EVERARD HARE, M D
Gower street, W C, Jan 16th 1905

THE CASE OF DR A D GRIFFITHS

To the Editors of THE LANCET

SIRS,—In your issue of Dec 17th, 1904 p 1733, under the title "A Vile Conspiracy," you published an account of an important action which was tried

held at Swansea last month the

Griffiths of Bridgend, a member o

the British Medical Association and of the Cardiff Medical Society The outstanding facts of the case will still be fresh in the minds of your readers and it will be remembered that Mr Justice Bray pointed out that Dr Griffiths s actions had been correct in every particula

summing up the judge intimat

that in their

The jury,

Dr Griffiths

with £500 damages, or five times as much as he had asked for

At a meeting of the South Wales and Monmouthshire branch of the British Medical Association subsequently held at Carmarthen a motion was passed unanimously expressing the sympathy of the branch with Dr Griffiths in his painful experience and congratulating him on the way in which he had justified its faith in his unblemished character A similarly worded motion was also unanimously passed at a joint special meeting of the Cardiff division and of the Cardiff Medical Society on Jan 4th and also at a meeting of the Incorporated Society of Medical Officers of Health At the joint meeting referred to it was made known that, as had been anticipated, none of the awarded damages will be realised by Dr Griffiths and that his legal expenses for the action amounted to something like £205 It was strongly felt that an opportunity should be given to his fellow members of the profession and others to express their practical sympathy with Dr Griffiths who with commendable courage and determination had successfully met so dangerous an attack not only on his own reputation but also on the *bona fide* status of the general practitioner

A committee was accordingly appointed to establish a fund to defray the unavoidably heavy bill of costs The committee consists of the chairmen and honorary secretaries of the Cardiff division of the British Medical Associa and of the Cardiff Medical Society respectively, Dr R S Stewart and Mr W Randall of Bridgend, with Dr A P Fiddian, 23 The Walk Cardiff, as treasurer Donations to the fund will be gratefully received and acknowledged by the treasurer or by the undersigned

We are, Sirs, yours faithfully,
THOS WALLACE, M D R U I,

R S STEWART, M D Glasg,
Superintendent Glamorgan County Asylum
Bridgend
EWEN J MACLEAN, M D Edin,
12 Park place Cardiff (Honorary Secretary
Cardiff Division British Medical Association)
Jan 15th 1905

The treasurer begs to acknowledge the following donations already received or promised —

Mr F W S Davies	0	10	6				

PRECOCIOUS LACTATION IN MALE INFANTS

To the Editors of THE LANCET

SIRS,—I think it is not yet generally recognised in the profession that the secretion of milk is natural in the newly born of both sexes

, attains its maximum between

after birth That the process

at upon the secretory activity of true acinous glandular structures has been proved histologically by De Sinétz,[1] Variot, Kolliker, Barfurth, and others It is to abnormal persistence or recrudescence of this physiological process that such cases as that reported by Mr R M McQueen in THE LANCET of Jan 7th, p 25 are due This type of precocity is more frequently seen in female than in male children and it is

but not invariably, accompanied by other signs

ous sexual development I have elsewhere cited

ses of this kind[2] In male children I have met with but very few similar examples A typical case was, however, reported a few years ago by Rogers[3] and another by Dalziel[4]

I am, Sirs, yours faithfully
W ROGER WILLIAMS
Clifton Bristol, Jan 7th 1905

CHLOROFORM ANÆSTHESIA COMPLICATED BY A FIT.

To the Editors of THE LANCET

SIRS,—I have been kindly permitted by Mr E Michels, senior surgeon to the German Hospital, to recount this case A man, aged 32 years, on Dec 3rd, 1904 fell from his bicycle while smoking, owing he said, to a sideslip, and the pipe stem was driven into his tongue He was not rendered unconscious He obtained treatment but as he did not improve he came to the German Hospital on the evening of Dec 8th and was admitted. The following afternoon he was taken to the operating theatre in order that his condition might be [illegible] under an anæsthetic. His breathing [illegible] considerably hampered by extensive swelling in the submaxillary region and of the tongue, the latter protruding somewhat between the teeth, I proceeded to administer chloroform by means of a drop bottle and Skinner's mask, very gradually and with a free supply of air. The patient appeared to take the anæsthetic well until the onset of the excitement stage, which, as Mr. Michels, who was standing by, remarked, took the form of a typical epileptic fit. I immediately withdrew the chloroform and in a few seconds the fit ceased, but with it respiration also, the patient quickly showing urgent signs of asphyxia. I advised immediate tracheotomy, which Mr. Michels at once performed, with the result that on just compressing the chest regular respiration was restored. An examination of his mouth was then made and the patient put back to bed. Shortly afterwards, in the presence of Mr. Michels, the patient had another apparent epileptic, fit, and again two hours later a third, remaining after each in a semi-delirious condition. He, however, died early the following morning, Dec. 10th, apparently from heart failure. There was no history of epilepsy or Bright's disease. The urine was not examined on admission as the patient did not pass any, having been without food or drink for some time previous to admission owing to difficulty in swallowing.

British Gynæcological Journal,

May, 190

[3] Brit Med Jour vol i 1897 p 29

[4] Glasgow Medical Journal, June, 1894

Post mortem the urine in the bladder was tested and found to contain one-fifth albumin, no sugar, and no blood; the kidneys were quite healthy, both to the naked eye and also microscopically; there were some congestion of the brain, œdema of the lungs, and some old pleural adhesions; all the other organs were healthy. There were an abscess in the tongue and purulent cellulitis of the neck.

The case, to my mind, is interesting for the following reasons: (1) What was the nature of the fits? Were they epileptic or were they uræmic? (2) Was the asphyxia the result of the fit or was it simply due to the condition of the man's neck and mouth?

I am, Sirs, yours faithfully,
ALEX. H. BREWER,
Jan. 13th, 1905. Honorary Anæsthetist to the German Hospital.

THE M.D. DEGREE OF THE UNIVERSITY OF ST. ANDREWS.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a paragraph in THE LANCET of Dec. 17th, 1904, p. 1763. The last Scottish Universities Commission, which finished its sittings in 1897, abolished the old power of granting ten M.D. degrees a year to practitioners of 15 years' standing and 40 years of age which the University of St. Andrews previously enjoyed.

I am, Sirs, yours faithfully,
E. WAYMOUTH REID,
Dean of the Faculty of Medicine, University of St. Andrews.
University College, Dundee, Jan. 11th, 1905.

THE ROYAL ORTHOPÆDIC HOSPITAL.

To the Editors of THE LANCET.

SIRS,—My attention having been drawn to the fact that the name of the hospital has been omitted this year from the Medical Directory, notwithstanding the fact that I made the annual return to the publishers, I shall be glad if you will kindly find space for this letter in the next issue of your journal in order that your readers may not form any wrong impression from this omission.

The hospital, having disposed of its site in Oxford-street and Hanover-square and the amalgamation with the National Orthopædic Hospital of Great Portland-street having, through the initiative of King Edward's Hospital Fund for London, been decided upon, is occupying temporary premises at 55, Bolsover-street, W., in proximity to the National Orthopædic Hospital, where its work is being carried on as usual.

Last year there were 3732 attendances of out-patients; and, by arrangements with the National Orthopædic Hospital, 133 in-patients were admitted and treated by the medical staff of this hospital. This arrangement will continue in force until such time as the amalgamation can be brought about and the rebuilding of the premises for the combined hospitals commenced.—I am, Sirs, yours faithfully,

Jan. 18th, 1905. TATE S. MANSFORD, Secretary.

THE BENEFITS OF LARGE ENEMATA.

To the Editors of THE LANCET.

SIRS,—The recent pronouncement of an eminent surgeon with regard to the treatment of obstinate constipation by ablation of the large intestine induces me to send you this record of my own personal experience, thinking it may be of value to some of your readers. I am now in my seventy-seventh year. In my early career when a medical student I contracted a very severe attack of dysentery at the time when cholera was very prevalent in London; and some years after on coming to London when greatly exhausted with work I was similarly seized and lost consciousness. The dysentery was most acute and I have a very vivid remembrance of the treatment, prescribed by the late Sir William Gull—viz., large doses of ipecacuanha, which certainly relieved the agony, but nauseated me to such an extent that my remembrance shudders at it still. More than 15 years ago I began to notice that the evacuations were getting smaller and smaller and that the difficulty in gaining effectual relief was becoming serious. I had a long and trying experience with aperients, small doses of castor oil, sulphur, hyoscyamus or belladonna, with soap or colocynth, and aperient waters, but these at first all seemed to do well enough but they became fitful in their time of operation, ar[illegible] practice this was exceedingly [illegible] became an intolerable nuisance. Moreover, it became quite clear that the contraction of what I presumed to be cicatricial in respect of the history was getting tighter and this led me to consider whether dilatation from below might not prove a very simple and easy means of ridding myself of these daily discomforts. This was the commencement of my use of enemata. I began with a pint of warm water the last thing at night, now more than 15 years ago. Before long I found that this was insufficient and I increased it to one and a half pints and then to two pints, and for some years lately some 56 to 60 ounces. I can always insure a good and complete relief of the bowels and generally I go to sleep about eleven o'clock and sleep till six. I manage to place myself in the posture as though I were lying down, so as to prevent the undue sagging of the intestine from the pressure of so large a quantity of fluid. After I began to use the large injections I gradually noticed that I was enabled to part with larger motions and now one of somewhat larger size proves to me that the calibre of the intestine in the part affected still keeps a grip upon the moving mass. I have not been able to see in my own case the injury thought to result from large enemata. I think there are many advantages. The emptying of the bowel of flatus, of feculent matter, not always perhaps in cases of this nature of the most salubrious type, brings with it refreshing and abundant sleep, removes headaches, and leaves the mind and body clear for the work and thought of another day. I have so greatly benefited by this method myself that I consider my lengthened experience of its value may be worthy the consideration of any who are contemplating the removal of their large intestine.

I am, Sirs, yours faithfully,
Jan. 17th, 1905. X

THE CAUSATION OF SEX.

To the Editors of THE LANCET.

SIRS,—The letter of "Medicus" in THE LANCET of Jan. 7th, p. 58, is not a solitary observation and his results are confirmed by other if less exact trials of the same general nature. There is little doubt that his observations are perfectly accurate so far as they go, but it is perhaps worth while to observe that there are two large factors which he does not mention though he has probably not overlooked them. He has been needlessly tender with the theory of the "predetermined" ovum.

Of these, the first is the relative age of the parents. It is a point of very considerable importance that the mother whose reproductive powers are senescent is extremely prone to produce male offspring only. This observation seems to be true not only of mammalia generally but also of aves; moreover, it is frequently seen to be true of homo and is a factor quite disassociated from any paternal factors. As a sort of corollary to this factor is the much less marked tendency of the immature sire to beget female issue. This tendency is less marked relatively but it is intrinsically evident enough and more frequent than the male tendency of the senescent mother though weaker in action.

The second great factor is the at present inexplicable tendency of certain female strains to produce female issue only. This factor is the strongest of all applying to homo, so far as long research will justify the statement. These observations, based on a combination of genealogical and medical studies, can easily be tested by anyone caring to work at the subject and one of the first points to attract the student's attention will be the frequency with which estates coming by the lass go by the same way, often for several successive generations, apparently until an exceptionally virile sire intervenes.

I am, Sirs, yours faithfully,
Jan. 12th, 1905. MEDICUS ALTER.

TAXATION OF HOSPITALS IN RESPECT OF MALE SERVANTS.

To the Editors of THE LANCET.

SIRS,—On behalf of the managing committee of a provincial hospital, I would beg you to find room in THE LANCET for the insertion of the following which bears upon a subject of great interest to all hospitals. During the month of December an Inland Revenue Form, No. 132, "Declaration for Local Taxation (estab., &c.) Licences," was forwarded to me to be filled up for the year 1904, the suggestion made by the local revenue officer being that one or more of the men engaged in the necessary service of this institution come within the "definitions" for *male servants* given on the said form. The contention of my committee is that all the men engaged here are employed on duties connected with the work and daily routine of the hospital and of the patients therein and not in any exclusive capacity, and, acting under my committee's instructions, I have made a return to that effect. We should be glad to hear through your valuable columns whether similar claim is made in the case of other hospitals either in London or in the provinces, and, if so, what is the nature of the return made from those institutions.—I am, Sirs, yours faithfully,

Jan. 10th, 1905. A HOSPITAL SECRETARY.

THE ASYLUM MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—I am glad to see by the letter of "M.B." in your issue of Dec. 31st, 1904, p. 1888, that at least one assistant medical officer has the courage to protest against the treatment which is meted out to his colleagues in the asylum service. The present unsatisfactory state of affairs has gone on quite long enough and in the interest not only of the medical staff but also of the patients committed to their charge a change is desirable, even essential. As long as the medical staffs of asylums are content to exist under their present conditions it is useless to insinuate that the fault lies at the door of those in authority, be they Commissioners in Lunacy, visiting committees, or even medical superintendents. The fault and the remedy lie in their own hand. But how few will ever take the trouble to place their views on paper. There are three distinct classes of assistant medical officers in asylums: (1) those who on entering it intend to remain in the service, devoting their lives to the study and treatment of mental diseases and thus in time becoming specialists; (2) those who, newly qualified, seek an asylum appointment in order that they may read for some further examination, on the passing of which they have set their ambition; or (3), those who unable to afford to enter general practice immediately they become qualified take an asylum post with the intention of waiting for a suitable opening in some district which may be known to them. When the opportunity presents itself they leave and are succeeded by colleagues with possibly similar views. To such as these an asylum appointment is but a means to an end. The end having been attained they depart and as a rule trouble no more about lunacy or asylums unless they be called on to certify a patient in the course of their general practice.

In the case of an assistant medical officer who enters the asylum service with the intentio[illegible] in it the case is very different. [illegible] and hope with an initial salary of anything from £120 to £150 per annum with the usual allowances. Three or four years pass by and he finds [illegible] diseases in addition [illegible] with which he star[illegible] notwithstanding his increased experience in a special science he is still drawing the same salary as when he entered the asylum service fresh from the hospital. His colleagues who are senior to him have little, if any, prospect of promotion in the future. True, they have had more years of service and consequent experience, but their salaries are very little in excess of what was considered sufficient remuneration for him when he entered the service without any special knowledge of lunacy. Then come weary years of waiting, hoping that one of his seniors may be promoted to one of the few vacant medical superintendencies which may chance to occur at rare intervals, and in most cases with resulting disappointment. His senior colleague, should he be unsuccessful in obtaining the post of medical superintendent in some other asylum, is in, if possible, a more hopeless plight. He has given the best years of his life to the study of mental diseases. What is his reward? A salary of perhaps £250 or £300 per annum and should he be over 40 years of age the probability that he may expect no further promotion or increase of salary. Moreover, there is a rule that no assistant medical officer can be married. (I believe there are one or two cases in which the senior assistant medical officer can do so if he likes.)

To the junior members of the staff this is not such a hardship as to their seniors. The pay and accommodation of a junior assistant medical officer put matrimony out of the question but when a senior comes to the age of, say, 40 years he may have some desire to have a home of his own after living for years in two rooms. With all respect for the authorities who govern asylums I would ask, What has a man done who has given the best years of his life to their service that he should be debarred from entering the matrimonial state should he so desire? As far as I can ascertain there is no other branch of the public service in which such a restriction is imposed on the permanent medical staff. It may be argued by those who favour the present system of enforced celibacy in the case of asylum assistant medical officers that a similar rule is in force in the hospitals and Poor-law infirmaries. To them I would point out that in neither case do the medical officers accept their appointments as a permanency. They, as a rule, leave after longer or shorter periods and enter general practice or one of the services, the experience which they gained during their term of office being of immense value to them in their future careers. With the asylum medical officer the case is absolutely different. After some years, as "M.B." correctly states, spent in the treatment of mental diseases a man has become a specialist and is thus more or less unfitted for general practice. The special experience he has gained in the asylum is of comparatively little use to him outside the walls, his duty for years having been more to treat mental diseases than physical ailments. Therefore there is no analogy between the cases.

With regard to the striking differences between the salaries paid to medical superintendents as compared with those of senior assistants I do not for a moment suggest that the medical superintendent, who is according to the Lunacy Act the chief responsible official of an asylum, is paid too [illegible] is that there is far too great a drop from [illegible] £800 to £1000 [illegible] his deputy who, it must be remembered, in the absence of the chief has to take the full responsibility at one-third, or even in a few cases less than, the chief draws. This increase of responsibility, if prolonged owing to the illness of the medical superintendent or other cause, is not always recognised by the committee, or [illegible] is doled out to the senior assistant [illegible] medical [illegible] It must [illegible] luties and [illegible] ischarged [illegible] assistant have now to be deputed to the [illegible] r last report strongly condemned the erection of these huge places, but despite this, committees ignore the recommendations of a body whom the public look upon as experts in such matters and continue to erect enormous costly "houses for the [illegible]ntion of the insane"—one really cannot call them hospitals for the treatment of mental diseases.

The question of leave is also the source of much complaint in asylums. The medical superintendent gets one month or in some cases six weeks annually, the assistant medical officers 28 days or perhaps in a few cases 31 days. Occasional leave is grudgingly accorded and then only one night can be spent outside the asylum gates unless a special appeal is made to the chairman of the committee who, unless there is some special reason given for wanting leave other than annual, may refuse it. Anyone with common sense must appreciate the fact that constant association with the insane is not conducive to exhilaration. Therefore a change of short duration at fairly frequent intervals, exclusive of annual leave, becomes not only desirable but even necessary to those who have charge of them. If the best men are to be attracted to the study of lunacy, which is becoming daily a more and more alarming factor in our social system, it behoves the authorities to amend the conditions of service of the assistant medical officers who have served them so long uncomplainingly. By this means alone can good men be induced to enter the asylum service as a permanency. Under the present system the junior post in asylums is usually sought after as a temporary abiding place where examinations may be read for or as a pleasant resting place until some better or more congenial employment turns up.

I am, Sirs, yours faithfully,

Jan. 13th, 1905. A. M. O.

L'INSTITUT DE VACCINE ANIMALE, PARIS.

(FROM A SPECIAL CORRESPONDENT.)

MOST of the vaccine used in France in general, and in Paris in particular, comes from the Institut de Vaccine Animale at No. 8, Rue Baller, Paris, a private foundation dating back to 1864 and due to M. Chambon whom I found still hale and hearty on the occasion of my visit. M. Chambon *has been succeeded in the directorate by Dr. Saint-Yves* Ménard, veterinary surgeon, physician, and professor of hygiene at the Central School of Arts and Crafts, who himself most kindly showed me his establishment.

Perhaps the most striking feature of this institution is that it provides for direct vaccination from the calf in Paris in all cases without exception. However carefully done, the processes for preservation and dispensing of a vaccine lead most certainly to its deterioration in strength, whereas the success of the immediate inoculation has been most constant and satisfactory. Vaccination in France may fortunately be said to know no enemies—a fact which is attributed by some to the non-existence in France of the elderly spinster, thanks to the male population being little depleted by the claims of empire; thanks also, perhaps, to the ranks of the potentially political spinsters being considerably thinned by sisterhoods. The people, therefore, are easily persuaded to be vaccinated and vaccination is brought freely down to their very doors by vigorous and enlightened municipalities such as that of the city of Paris. In every one of the 20 boroughs (*arrondissements*), usually in the charity offices (*bureaux de bienfaisance*) at the town halls, and in every one of the chief hospitals free vaccination directly from the calf is performed once a week on one particular day and at one particular time of day, and at the Academy of Medicine it is performed three times a week, the complete list being printed in convenient form on quarto paper and widely advertised. *Every night the unvaccinated in the shelters* are vaccinated. If anywhere a case of small-pox breaks out the fact is telephoned to the Vaccine Institute, an official is sent on a bicycle to impress on all neighbours the need of vaccination and to post notices,[1] and a public vaccination is held on the spot, often in the street, the next morning. For the purpose of vaccination the calf with its fourth, fifth, or sixth day pustules is sent down in one of the eight cars specially constructed something like hunt carts for the purpose, in charge of a driver accompanied by a medical officer. Under proper precautions most channels of contamination are thus removed and the figure for successful results of this direct calf vaccination is officially given as 100 per cent. Exact returns for the lymph distributed in tubes are unobtainable. The vaccinations performed by the institute for the ten years 1890-99 are as follows:—

—	Vaccinations.	Revaccinations.
1890	35,496	55,734
1891	37,369	85,055
1892	36,026	58,803
1893	40,813	187,206
1894	38,140	207,034
1895	36,023	120,006
1896	36,827	93,261
1897	38,696	102,931
1898	39,012	104,712
1899	36,986	105,546
Totals	375,370	1,125,288

These figures are made up as follows:—

—	Vaccinations.	Revaccinations.
Hospitals	116,863	411,284
Boroughs	212,481	47,553
Houses infected by small-pox	5,384	89,594
Public schools	1,628	455,611
Various	39,014	121,246
Totals	375,370	1,125,288
Grand total	1,500,658	

This for a population of 2,500,000 gives an average of 6 per cent. vaccinations or revaccinations per annum.

This service involves the employment of four medical men besides the director, the skilled staff being completed by nine assistants and an accountant. The eight cars imply a further equipment of horses, drivers, and stable-hands, but they save the processes of preparation, storage, and distribution of the lymph thus used. The Vaccine Institute accordingly contains not only a waiting room, a couple of vaccination rooms, a laboratory for the preparation and storage of vaccine, and offices for packing and clerical work, but also stabling for 20 calves and eight driving horses, coach-house, and a room for inoculating the calves. As this is all confined in a small area it speaks well for the cleanliness of the arrangements that there is no suspicion of a stable smell about the house. One enters first by the hall into the waiting room, the walls of which are a museum of Jenner lore. There is a French portrait in oils of Jenner, recently acquired by Dr. Ménard, and dated the thirteenth year of the republic (1802), holding in his hand a treatise, "Sur la Vaccine." But Jenner never was in France. There is an autograph letter from Jenner to his son Robert dated London, Nov. 2nd, 1814, when he was tediously awaiting by Royal command the arrival of the Emperor of Russia and entertaining parties of from 12 to 15 at breakfast. There is a steel engraving of a French portrait of the English physician Wilmotte who personally brought the first vaccine to France. There are numerous portraits and caricatures in honour or in detraction of the pioneers. Passing through this room the visitor enters the vaccination rooms, carefully built and simply fitted up with due regard to the needs of asepsis, mercurial and boric lotions being also provided, and outside is a clean tiled recess in which the vaccine is taken from the calf at the moment of operation. After being once used no pustule is employed again.

Next one comes to the stable for 10 calves, which is warmed by hot-water pipes and well ventilated, the most comfortable and the cleanest stable and the cleanest calves that I have ever seen The latter are all of the same breed Limousins of a light bay colour, aged between five and eight months, and weaned some time previously, so that they live well on hay bran, and oats without being subject to diarrhoea They are hired for the purpose at 40 francs apiece and are brought straight from the country farms to the farm belonging to the institute outside the city whence after from three to ten days' observation they are transferred directly to the Rue Baller Here they are well washed every morning and the whole of the belly and both flanks are well shaved before inoculation presenting a clean surface of white skin After being thoroughly cleansed this surface is inoculated along vertical incisions an inch long and two inches apart in rows not immediately one above the other, and after four or five days—a day longer than in a sucking calf—the pustules are ready to provide vaccine for from five to 20 persons each Sixth day pustules are chiefly used for the preparation of vaccine pulp From 350 to 450 calves are used in a year After use they are handed over to the butcher for slaughter

---

[1] The following is a translation of the notice.—CITY OF PARIS.—The inhabitants of No. ...., ... Street, and of neighbouring houses are informed that the municipal service of vaccination and revaccination by calf vaccine will be at their service in this house on .... They are invited, in their own interests and that of their families in order to avoid the spread of small-pox, to obey the directions of the medical men who will perform these operations. Those who are unable to be present are informed by the following table of the places, days, and hours of free vaccination. Small-pox is an eminently contagious disease. Vaccination and revaccination "are the only means of preventing and curtailing the epidemics of small-pox."—(Opinion of the Council for Health and Sanitation of the County of the Seine.) Beneath this is posted the weekly time-table of free vaccinations.)

After many experiments it has been found that vaccination of the calf with glycerinated vaccine pulp of two months standing gives the purest eruptions and this is now always used the vaccine being tested by 48 hours culture on sloped gelatine The pulp consists of the whole tissue of a pustule transferred directly, under proper precautions after washing with boric lotion, into glycerine in a nickel bowl It is then triturated and mixed with more glycerine up to an equal part in a special Latapie machine simple and easily sterilised, which has displaced the Dresden Chalybaus machine in use in most vaccine institutions It is then transferred into a sterilised glass flask fitted up like the common wash bottle of a chemical laboratory A clip on the distal end gives control of the outlet, a valvular ball of thin rubber like that used for administering chloroform in operations about the mouth, by occasional inflations by hand keeps up the pressure inside the bottle and a slender nozzle fits into the tubes to be filled The tubes in common use are of two sizes respectively for four and for 20 vaccinations and are therefore more easily managed than the tubes for single operations They are sterilised at 200° C in a Wiesnegg gas heated stove When filled the ends are sealed in a blow pipe worked by air pressure from a tall slender water cylinder in the corner of the little laboratory The tubes are thrust into cotton wool in small metal cases like the case of a clinical thermometer and this fits tightly into a cylindrically tunnelled plain piece of wood which is labeled and goes by post for five centimes

Vaccination is compulsory for all patients in all hospitals except under exemption by medical orders, it is also compulsory for all those in the municipal shelters who are not provided with a vaccination certificate And now by Article 6 of the new Public Health Law[2] dated Feb 15th 1902 as the readers of THE LANCET are aware[3] vaccination is made compulsory during the first the eleventh and the twenty first years of life all children in the schools and recruits under the conscription law being revaccinated Schoolmasters furnish lists of children requiring revaccination The operation if unsuccessful, is repeated always three times The twenty second instead of the twenty first year should have been prescribed as recruits do not join the army till the end of their twenty first year and until this mistake is rectified there will be some difficulties The method by which the new law is to be enforced is laid down in a presidential decree of July 27th 1903 and detailed in a ministerial circular to the prefects The authority is the prefect of each department, the autocratic representative of our county council acting under the advice of a general council and of a departmental council of health The prefect nominates and controls the medical men the midwives and the remaining *personnel* of the service The general council advises upon the creation of special vaccination areas upon the time table, and upon the remuneration of vaccinators which averages at present about half a franc for each operation But the Academy of Medicine and the national advisory committee of public health actually determine the general duties of vaccinators and advise the Minister of the Interior as to the control of establishments for the preparation of vaccine Various measures are prescribed for securing the satisfactory operation of the law and it will be interesting and instructive to us in England to watch its results now that it has for the first time come into force with the new year

Result of vaccinations—The report of the director as to the efficiency of his work is as follows ' In our calf to arm vaccinations complete success is the rule With vaccine preserved in tubes the proportion of successes is always about 100 per cent, except for an occasional accident Our vaccine institute is a private establishment charged with the public services of the city of Paris and county of the Seine (for hospitals and charity offices) As to the number of tubes distributed by other vaccine establishments I have no information

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

The Bombay Exhibition (Health Section)

THE large exhibition now being held in Bombay possesses an important health section at which demonstrations on the manufacture of the plague prophylactic form a leading feature but in addition demonstrations are given on the method of extraction of snake venom on the defects in water fittings and on the prevention of waste of water, and on the bacteriological treatment of sewage The novelty connected with the plague prophylactic is in the bottling otherwise it is manufactured in the old way The flask of "vaccine' ready for bottling is fitted with an apparatus previously sterilised, which draws off a portion into a glass bulb An indiarubber stop seals the exit from the atmosphere The new form of phial is made to terminate in a fine point which is sealed after the phial has been sterilised and exhausted of air The point of the phial is thrust through the indiarubber seal into the bulb of ' vaccine' fluid and the point is broken off by impinging against a small steel bar The vaccine rushes into the phial which when filled is withdrawn and at once sealed Successive phials are filled until the flask is emptied By this process the prophylactic does not come in contact with the air The phials are kept for ten days and a percentage of them is tested before being issued A sample of This is accomplis phials which conta small proportion of the fluid is thus retained from each phial Another interesting exhibit consists in models of some of the worst chawls of Bombay and in contrast some of the new buildings erected by the Improvement Trust Nothing could better illustrate the amazing development which is going on in Bombay The municipality has organised large models in bas relief of the Tansa waterworks of the island of Bombay, models of the system of house connexions of the water filters and of a new detritus trap These exhibits will possess a very high educational value The health section of this enterprising exhibition is a great success

Further Rise in the Plague Mortality

The plague returns for the week ending Dec 17th show that throughout India there were 18,284 deaths This is a rise of 855 over the previous seven days

The New Director General

Much surprise is felt at the announcement that the post of Director General now held by Sir Benjamin Franklin, I M S, will fall to Colonel Gerald Bomford I M S, who has many seniors and has only recently left his post of principal of the Calcutta Medical College It is the opinion however of many that he possesses great administrative capacity

Lathyrism

The report of the inquiry into the occurrence of lathyrism has been recently published and shows that the common belief which connects the prevalence of lathyrism with the long continued and excessive use of the vetch known as Kesari dal is correct It was found that the paralysed persons had eaten lathyrus in large quantities and for a long time and that no one was paralysed who had not eaten it. Many who found paralysis coming on gave up this vetch as food and recovered.

Further Scientific Investigation into the Etiology of Plague.

On his arrival at Bombay Lord Curzon announced that he had been in communication with the heads of the Royal Society and with the authorities of the Lister Institute on the subject of further scientific investigation into the etiology of plague. The Punjab Government has made official proposals to the Government of India and the Government of India has forwarded a dispatch to the Secretary of State. At the same time the corporation of Bombay had arrived independently at the same conclusion —viz., that further inquiry was urgently needed. The concurrence of authoritative opinion arrived at without consultation shows how widely the opinion is held that more should be done to discover means for combating this increasing scourge. We may therefore expect to hear shortly of the definite appointment of a further plague commission. It is to be hoped that all the members will be scientific investigators and that no civilians will be nominated. There are no questions of administration or of policy requiring their presence and the inquiry needed is a purely scientific one.

Dec. 31st, 1904.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Floodgate-street Area.

THE Floodgate-street area was again the subject of public comment at the annual meeting of the Birmingham magistrates. Alderman Cook, the chairman of the health committee, drew the attention of the magistrates to the report of the medical officer of health on the area, in which he attributes the high mortality to excessive drinking; he moved that all magistrates be supplied with a copy and said that the very least they could do was to give it a full and serious consideration. This was seconded and Mr. A. M. Chance, the chairman of the licensing committee, in supporting it, took the opportunity of stating how important and able a report he deemed it. An influential meeting of the citizens' committee, which was largely instrumental last year in directing attention to the subject, has also met to consider what steps should be taken in view of the Brewster sessions to be held next month. The meeting passed no resolution, deciding to await indications of the policy likely to be adopted by the magistrates. The laying on of a supply of water to each house in the courts of this same area was considered at the last meeting of the Birmingham water committee. A sub-committtee which had been appointed to consider a communication from the health committee on this question reported that the use of standpipes for courts led to a great waste of water owing to the users allowing the taps to run more or less continuously and that now that the Welsh water-supply was available there was no reason—so far as they were concerned—why a supply should not be laid on to each house. The report was adopted as the answer to the health committee.

Drunkenness during the Past Year.

At the annual meeting of the magistrates Mr. Chance, the chairman of the licensing committee, referred to a report received from the chief constable relating to the number of persons convicted for drunkenness during the years 1902, 1903, and 1904. In 1902 the number was 2576, in 1903 3064, and in 1904 3478. Commenting upon these statistics Mr. Chance thought their unfavourable nature was attributable to the Act of 1902 and to its more stringent enforcement by the police. The statistics, in his opinion, showed that, much as they all desired a reduction in the number of licences, it was not the only factor to be considered. He did not believe that drunkenness was on the increase in Birmingham. A communication from the Home Department about the disregard shown for the regulations concerning the black list drew forth the opinion that the list had proved an utter failure, that persons who had been placed upon it were brought up almost daily. The Brentry Homes for Inebriates was the subject of a special report to the magistrates by Mr. J. C. Lord. He expressed himself as satisfied with the sanitation and administration of the homes and with the health and behaviour of the inmates. He regretted that of the 15 beds allotted to Birmingham only eight were at present filled by local cases; the more so because he was of opinion that more good would accrue from the sending of suitable cases to a reformatory than by sending them to prison. He would like to see those starting on a career of drunkenness sent there and wished to impress upon the younger members of the bench the importance of looking carefully into all cases with a view to this course of action.

The Birmingham Water.

The medical officer of health submitted to the water committee at its last meeting the results of analyses of samples of the Birmingham water. A sample taken at Frankley before filtration on Dec. 15th was found to possess a marked purity and to show less colour than the previous ten samples. The persistent brown colour heretofore has occasioned a certain amount of anxiety among the more nervous of the community.

Handsworth and Medical Relief.

At a meeting of the West Bromwich board of guardians it was decided to divide the Handsworth parish into two districts for medical relief purposes—viz., No. 1 district to consist of Sandwell, Soho, and Murdock wards; and No. 2 district of Birchfield and Heathfield wards and the parish of Perry Bar. The reason for the division is the enormous growth of the district during late years. In consequence of the division two medical officers will be appointed at salaries of £70 each per annum instead of one, as at present, at a salary of £110.

Health of the City.

The health returns show that for the week ending Dec. 31st, 1904, the death-rate was 25·3; for the week ending Jan. 7th the death-rate was 21. The zymotic death-rate for the former week was 1·9, as against 0·7 for the first week of this year. The reduction in the zymotic death-rate was due particularly to the decrease in deaths from diarrhœa and pulmonary tuberculosis. At the end of last week there were 193 patients in the scarlet fever hospital, as compared with 211 at the close of the previous week, and the typhoid fever wards contained 19 patients as against 26.

Health of West Bromwich.

The medical officer of health of West Bromwich has just issued his sanitary summary for the year 1904. This shows a birth-rate of 33·6 and a death-rate of 15·9, the decennial averages being 35·2 and 18·6 respectively.

Bequests to Local Charities.

By the will of the late Mr. William Ansell of Sutton Coldfield the local charities have benefited to the extent of £5000.

Jan. 16th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Infantile Death-rate at Dukinfield.

AT Dukinfield 1 in every 3 children born dies in infancy. It seems as if all efforts to reduce this mortality were fruitless. It is said that the county authorities and Mr. F. Vacher, the medical officer of health, "have repeatedly roused the ire of the town council by their scathing comments" on the town's record of mortality. The suggestions of the county council health committee have been put in operation without reducing the death-rate. The sanitation, under the care and guidance of Mr. Bancroft, the chairman of the sanitary committee, has been greatly improved. "A health-giving breeze sweeps through the town from the adjacent moors and the water-supply is second to none in its purity." Four or five years ago it was thought that the milk-supply might be faulty and at the wish of the county council a sterilised milk depôt was opened. This new venture tickled the sense of humour of the people who, though living in Cheshire, closely resemble their near neighbours of Lancashire in this peculiar quality, which is quaint and racy if not grounded on knowledge; and this venture of sterilised milk was killed by ridicule in about two years. It is said, indeed, that the infantile death-rate was not lower but higher during the use of sterilised milk, though there was probably no connexion between them. Last month the deaths were equal to 325 per 1000, the highest in Cheshire. When all general influences noxious to health have been so far as possible removed without apparent result the inquiry should go nearer home The population is a manufacturing one the mothers work in the mills, and the infants are of necessity left to the care of others Mothers and caretakers are, with occasional exceptions steeped in the grossest ignorance The natural food of the child is not forthcoming, for the mother in most cases is a poor creature, unable to furnish it and the child receives all kinds of substitutes most of them hurtful It is difficult to root out the ignorance and [illegible] more especially in a people [illegible] is called "independence [illegible] ing ' meddled with, but perhaps more may be hoped for in the next generation if as is foretold the education given in the elementary schools is to be so changed as to be really useful to the children in their after life Some instruction in the simple laws of health and in the care and feeding of young children may surely be given In the meantime a society like that of the Manchester Ladies Health Society may by its tactful and sympathetic ministrations do something to lessen the ignorance and in some cases the apathy, underlying the waste of life that has become so common as to be almost disregarded

Wanted to Sit on the ' Live Rail

The dangers surrounding the path through life seem to increase with every application of science and the electric or electrified railway may be taken as an illustration About a week or ten days ago two drunken fellows were found trespassing about midnight on the Lancashire and Yorkshire line near Southport This portion of the line is ' electrified [illegible] it on the live rail [illegible] too drunk to decline [illegible] is foot on it adding that he was prepared to meet his Maker A pointsman telephoned for help and with the aid of three porters the men were got off the line safely, though they several times lurched in dangerous proximity to the ' live rail Each man was fined 20*s* and costs which may help to remind them of the dangers of the "live' rail and of being drunk when near it But apart from any question of drunkenness there is no doubt that with the increasing use of electrical appliances dangers are multiplied and it is greatly to be desired that more care should be taken to diminish these dangers as much as possible

Jan 17th

LEEDS

(FROM OUR OWN CORRESPONDENT)

Annual Report of the Medical Officer of Health

AT the first meeting of the sanitary committee of the Leeds city council Dr J Spottiswoode Cameron presented his annual report for 1904 from which it appears that the birth rate was 28 and the gross death rate was 18 the average birth and death rates for the last ten years standing at 31 and 19 respectively The ratio of deaths under one year to 1000 births is 176, as against an average of 171 for the previous four years There had been 64 cases of small pox with two deaths

Leeds Crematorium

Messrs Toisoul Fradet, and Co of Paris have supplied the crematorium which has just been erected at Lawnswood Cemetery with one of their lighting gas furnaces and the experimental trials, as well as the first actual cremation which took place recently have been eminently successful This is the first furnace of its kind erected in this country and it is claimed that the temperature can be regulated to a nicety and the amount of hot air admitted also so that at first rapid desiccation of the body takes place and then complete combustion occurs on a lowering of the temperature with the admission of an extra amount of hot air A crematorium on similar lines is shortly to be erected at Bradford

Small pox

Small pox has been prevalent in some of the districts around Leeds, notably in Dewsbury and the neighbourhood Last week there were 21 cases notified in Leeds and removed to the hospital These were mostly due to an outbreak at a common lodging house and at houses in the insanitary area At the end of the week there were 28 patients under treatment in the hospital as against ten at the end of the preceding week For some time the resident staffs of the infirmary and dispensary have been especially on the alert for the possibility of cases turning up in the out patient rooms and several cases have in this way been detected and dealt with The infirmary has refused admission except in cases of emergency to patients coming from townships known to be infected and the attendance of patients from infected areas at the x [illegible] en suspended On [illegible] en 90 and 100 of [illegible] medical officers, nurses porters wardmaids and servants—had not been revaccinated for three years, which had been selected as a working time limit of safety, and these were all revaccinated except three of whom two were leaving the service of the infirmary and had been vaccinated five years ago

The Sale of Poisons

The Bradford stipendiary has delivered his judgment in a case tried before him on Jan 4th Six local registered druggists were summoned for an alleged infringement of Sub section A of the 17th Section of the Pharmacy Act of 1868 which makes it unlawful to sell any poison to any person unknown to the seller, unless introduced by some person known to him The summonses were taken out by the secretary of the Patent Medicine Vendors and Drug Stores Association The general issue was dealt with on one summons and it appears that a box of Rankin s ointment which contains veratrine was supplied to a woman without any questions being asked It was advanced for the defence that the ointment was a poisonous compound prepared for the destruction of vermin and that such a preparation though containing a scheduled poison was exempt from the section of the Act under which the summons had been taken out The stipendiary convicted and imposed a fine of £2 with £1 14*s* 6*d* costs and intimated that he would consider the question for the statement of a case if application were made to him within seven days

Grants to University Colleges

A memorandum from the Treasury dealing with the subject of increased grants to university colleges states that the amount voted for 1903 04 was £27 000 and that the amount voted for 1904-05 is £54 000 The original grant of £27 000 is distributed among the various colleges as before Of the additional £27 000 a sum of £9000 is to be distributed substantially on the old basis, a further sum of £9000 is to be similarly allotted for the year 1904-05 only as the present year is of a [illegible] anges which the committee [illegible] of distribution cannot be [illegible] ffect The committee reserves its propo als as regards the remaining £9000 The effect of this so far as the University of Leeds is concerned is that the grant now stands at £4000 as against £2300 for last year

University of Leeds

Professor R H Hartley having resigned the professorship of public health the council of the University has offered the chair to the medical officer of health of the city Dr Spottiswoode Cameron A demonstrator in the subject is also to be appointed

Scholarships for Medical Students

The following rules embody some changes in the regulations 1 The medical scholarship of 64 guineas which covers the complete course of lectures at the medical school, is now to be awarded on the result of the joint matriculation examination under certain conditions 2 The infirmary scholarship of the value of 40 guineas given by the faculty of the infirmary and covering the course of clinical instruction is to be awarded under certain conditions on the result of the first M B examination held in June of each year 3 As heretofore medical students who are studying also for the B Sc may hold the Akroyd and Brown scholarships the Leeds City Council scholarships, and certain free studentships under the grant of the city council

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary: Annual Report.

THE annual report of the Edinburgh Royal Infirmary reminds the public that the present buildings have been in occupation for 25 years. The growth of the institution is abundantly illustrated by the figures given in the report. In 1880 the number of indoor patients treated was 5315; in 1904 they had reached a figure almost double that—namely, 11,125. The number of outdoor patients treated had more than doubled, having risen from 15,000 to 33,412. The ordinary income had risen from £21,541 to £33,814 and the ordinary expenditure from £27,818 to £49,808. The number of patients treated in the infirmary during the year with which the present report deals was 11,125; of these 858 died. There was an increase of 671 over the preceding year. The average daily number of patients was 810. The ordinary income amounted to £33,814, an increase of £1128 over the previous year. The ordinary expenditure amounted to £49,808, or £2207 above that of the preceding year. Important changes have been decided upon in the surgical out-patient department. There had been a good deal of criticism of this department in the Edinburgh evening papers and the result has been as follows. The department is to be under the continuous supervision of one of the assistant surgeons, these gentlemen taking the work in rotation for four months at a time and during those months they are to be relieved of all other duties in the infirmary. The surgeon on duty is to be assisted by such house surgeons, dressers, and nurses as may be necessary and he is to have two day and two night porters. A house surgeon is to be constantly present in the department both day and night. In addition a small operating theatre is to be added to the department. The report, of which the foregoing gives the most important details, was submitted to a meeting of the court of contributors on Jan. 2nd, the chair being occupied by the Lord Provost. In submitting the report the chairman referred to the decision of the meeting of contributors with reference to the rule of an age limit for the honorary staff. He thought it was understood that the rule was not to be applied to the present professors or to the members of the ordinary staff in the second or third terms of tenure of office and the board was acting on that presumption. The board has thus made a rule applicable to all future appointments and one which will affect the tenure of office of only two or three of the present assistant staff. It would have saved hours of controversy and weeks and months of heart-burning if at the outset it had been intimated that all present holders of office were to be exempt from the new rule; as it is, peace now reigns for the few victims of the new rule appear to be indifferent to its effect. Time alone can show whether the infirmary is wise in making this rule for its physicians.

University of Edinburgh: Annual Report.

The annual report of the University of Edinburgh shows that there were 1480 students of medicine during the year: of these 683 belonged to Scotland, 352 were from England and Wales, 113 from Ireland, 74 from India, 238 from British Colonies, and 20 from foreign countries. The number of women attending extra-academical lectures with a view to graduation in medicine in the University was 116. During the year the degree of M.B., C.M. was conferred on four candidates; that of M.B., Ch.B. on 161 (including 12 women); and the degree of M.D. on 61. With regard to the Carnegie foundation it is stated that students have availed themselves of it to take more classes than they would have otherwise done. A lectureship on the Practical Application of Anæsthetics has been established and also one on Infective Fevers. Dr. T. D. Luke has been appointed to the former, and Dr. J. O. Affleck and Dr. C. B. Ker of the City Hospital to the latter.

Typhus Fever in Aberdeen.

In his monthly report, which was submitted to the public health committee of the town council on Jan. 11th, Professor Matthew Hay, the medical officer of health, stated that on Dec. 20th, 1904, a case of supposed measles in a labourer residing in Shoe-lane was reported as requiring removal to the City Hospital on account of the patient having exhibited symptoms of delirium. At the hospital the man was found to be suffering from typhus fever. No other case of that disease was known to be in the city at the time and, indeed, no cases had been reported since 1899. There had, however, been some weeks previously among the children of the patient what were regarded as cases of measles, but as measles is unusually prevalent at present it could not be definitely assumed that these were cases of typhus fever. In the week following the admission of the patient to the hospital his wife became ill with similar symptoms and she was at once removed to hospital. Two days subsequently a case of supposed typhoid fever was notified from a house in West North-street and the active inquiries which were then made resulted in tracing a total of some 40 cases of illness with 10 deaths, now attributed to typhus fever. The earliest attacks seemed to have occurred in a house in Martin's-lane, where the father of the family had died so far back as Oct. 5th and where there had since been several cases of a similar illness. It is proper to state that owing to the rare occurrence of typhus fever in recent years comparatively few medical men have ever seen cases of it and are therefore less ready in recognising them when they unexpectedly occur, especially as the rash is often ill-defined and is difficult to see in dingy, badly lighted, and in many cases dirty houses, such as those in which the present epidemic had its beginning. The less serious cases in the children were not always seen by a medical man and the more serious cases in grown-up persons had the typical characters of the disease obscured in several cases by inflammation of the lungs, to which the general illness was regarded as being due.

Turner Memorial Hospital, Keith.

The annual meeting of the committee of the Turner Memorial Hospital was held at the hospital on Jan. 9th. The medical officer, in his report for the past year, said that 66 patients had been admitted, of whom 43 had recovered, 11 had improved, five had died, and there were seven in the hospital on Dec. 31st, 1904. Of the 66 admissions, 43 had come from the parish of Keith and seven from the parish of Grange. The treasurer, in his report for the year, stated that a sum of £285 stood to the credit of the capital account. The revenue for the year amounted to £592 and the expenditure to £450. The directors of the hospital afterwards met. It was decided to allow patients from the participating parishes who were suffering from infectious diseases to be admitted to the hospital at the rate of 12*s*. 6*d*. a week.

Action against a Medical Man.

IN the Nisi Prius Court on Jan. 16th, before the Lord Chief Justice and a special jury, the case of Hanrahan *v*. Parry was concluded. The plaintiff, Miss Frances Hanrahan, a barmaid residing in Dublin, sued the defendant, Dr. William Harrop Parry of Llanrwst, Denbighshire, to recover damages to the amount of £1500 for breach of promise of marriage. The Lord Chief Justice commented severely on the conduct of the defendant who proved to have been for years a married man. The jury awarded the plaintiff £300 which the Lord Chief Justice said was a proper verdict.

Erection of a Sanatorium for Consumptives in the County of Cork: Public-spirited Action of Local Authorities.

Some time ago a movement was inaugurated with a view to induce various public boards in Cork city and county to join together for the purpose of erecting and maintaining a sanatorium for consumptives. The local branch of the National Association for the Prevention of Consumption took up the project energetically. It sent deputations to the borough council, the county council, and to all the urban and rural district councils. The members of the deputations emphasised the importance of checking the ravages of consumption. They pointed out the terrible destruction of human life caused by pulmonary tuberculosis and what an advantage it would be to have an institution in which the disease could be arrested in its earlier stages. They referred to the contagiousness of the malady and expressed a strong opinion that the establishment of a sanatorium would within a short time mean a saving in the rates. The various public boards, 28 in number, took an intelligent view of the situation and agreed to strike a rate of 1*d*. in the £ for the erection and maintenance of a sanatorium. A Bill has been passed through Parliament giving them the requisite powers and a committee of 56 members held their first meeting on Jan. 7th. They appointed Mr. D. D. Donovan, medical officer of health, and Dr. P. J. Cremen to assist them in the selection of a site. It is also proposed to call in an expert to consult with those two gentlemen. Mr. Barter, St. Ann's-hill, Blarney, has very generously promised a contribution of £500 towards the erection and equipment of the sanatorium. An institution of the kind is an absolute necessity, as pulmonary tuberculosis is unduly prevalent in the city and county. The public boards concerned deserve every credit for their benevolent and far-seeing action.

Physical Degeneration and Bad Hygiene.

Under the auspices of the Irish Association for the Prevention of Intemperance Professor G. Sims Woodhead delivered a lecture on Jan. 9th in the theatre of the Royal Dublin Society on the question "How far is Physical Degeneration the Result of Bad Hygiene and Intemperance?" Dr. James Little, who presided, said that nobody could walk through the streets of Dublin without noticing that a degeneration had taken place in the physique of our people. He did not think them worse than the people, say, in Vienna but they appeared to him to be much inferior to the workmen in Berlin and the north of Germany. Professor Woodhead in his lecture dealt chiefly with the conditions on which the nutrition of the body depended such as fresh air, suitable food properly cooked, temperance, &c. As regards the increase of lunacy in Ireland, he said that it did not seem to go on side by side with increase in drinking, as was the case in England and Scotland, where increased consumption of alcohol among certain classes was invariably associated with a corresponding increase in lunacy. Sir Francis Cruise proposed a vote of thanks to the lecturer which was seconded by Sir Lambert Ormsby. Mr. T. W. Russell, M.P., in proposing a vote of thanks to Dr. Little for presiding, said that in dealing with the situation in Dublin they should not forget that the city contained a greater number of the very poor than any other of the same population in the United Kingdom, and when he thought of the awful state of affairs in the tenement houses, how the people lived in single rooms, how they were fed—or rather not fed—he felt inclined to wonder that they were ever sober.

Rainfall in Belfast in 1904.

Meteorologists will be interested in the following particulars as to the rainfall in the Belfast district for the year 1904. The information is based on the returns from Queen's College, Belfast, and from Goschen, Springfield. The latter place is in the neighbourhood of Belfast, about 150 feet above sea-level, as compared with Queen's College, which is 68 [illegible] total fall for the year 1904 was at [illegible] ·841 inches and at Springfield it [illegible] fell at the lower level (Queen's College) on 197 days, while at the higher level it fell on 293 days. The total rainfall in 1904 was below that in 1903, when the figures were 42·339 inches, the highest recorded for over 30 years. During December, 1904, the rainfall was 2·957 inches, the highest previously recorded for December was 8·86 inches in 1876, and the least was 1·81 inches three years later. A rather interesting fact has been made out at Queen's College and that is that the old rain-gauge statistics for the past 40 years may be regarded as absolutely accurate. Last year the College authorities placed in the grounds a new Snowden rain-gauge one foot from the surface. The readings from this were narrowly compared with the old one seven feet from the surface and no difference has been found. The driest month in 1904 was October; rain fell more frequently in April than in any of the other 11 months. August was a wet month and in addition to the gauge registering the greatest rainfall, on 21 days there were downpours. The highest temperature during the year was recorded on July 29th—71·5° F. in the shade—and the lowest—25·3° in the shade—was on March 11th. There were 40 days less rain than in 1903. The greatest rainfall in 24 hours was on Sept. 2nd—0·860 inches—and the average for the past 39 years was 35·512 inches. The greatest velocity of the wind was on Oct. 5th and 6th; there were thunderstorms on four days during the year, that of July 12th taking place between 7 and 8.30 in the evening. The last month of the year was the finest for many years and 1904 the best for 11 years.

Royal Victoria Hospital, Belfast.

The board of management, on the recommendation of the medical staff, at its meeting on Jan. 4th, appointed Dr. T. Houston to act as pathologist for the remainder of the winter session.

The Belfast Cripples' Home.

The bazaar on behalf of the Cripples' Home, which was opened on Dec. 6th, 1904, by Lady Dudley and at which His Excellency the Lord Lieutenant was present, has, after all expenses have been paid, realised a sum of £7300. As showing the interest taken by the poorer classes in the effort upwards of a quarter of a million pennies were received.

The Estimation of Carbon Monoxide in the Atmosphere.

AT the meeting of the institute which was held on Jan. 9th M. Armand G[illegible] bert. Levy and M. [illegible] the estimation of [illegible] test will show the [illegible] tion of 1 part in 100,000 parts of air. The method is as follows. The suspected air is passed over per-iodic acid contained in a U tube kept at a temperature of 80° C. The carbon-monoxide if present decomposes the per-iodic acid, setting free iodine. M. Gautier fixes this on copper and estimates the amount by weighing while M. Levy and M. Pécoul pass the air and the iodine through chloroform which takes up the latter. The amount of iodine is estimated by a colorimeter scale and from the amount of iodine the quantity of carbon-monoxide is deduced. The method is absolutely accurate and no other element present in the atmosphere will reduce per-iodic acid. By its aid the atmosphere in the neighbourhood of a suspected stove can easily be examined in plenty of time for the necessary precautions to be taken.

Jan. 17th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Plague at Suez.

SIX cases are now under treatment at the infectious hospital and are recovering; all are bubonic, two femoral, one axillary, two cervical, and one pre-auricular. One pneumonic case was found dead and since then a second patient has been taken ill with pneumonia in the same house. The first case was found on Dec. 10th and since there have been ten others. This is the first time plague has spread in Suez for at least 60 years, though individual cases have often been imported during the last few years. This time it may have arrived with cargo from India, for one dead rat was discovered in a bale of goods, or it may possibly have come with merchandise from Upper Egypt. All the cases so far found have been in the same quarter of the town and there has been a considerable mortality among the rats. The rats are now being poisoned and trapped as far as possible. Dr. J. E. Creswell has injected two bubonic cases with the anti-plague [illegible] Pasteur Institute in Paris; in both the [illegible] not again rise and the glands [illegible] inful though one of them subsequently suppurated. This serum is sent out with instructions in six languages. It is prepared from immunised horses [illegible] mended both for prevention and for treatment. [illegible] used every ten [illegible] centimetres are [illegible] times. In bad [illegible] cases it is suggested that a double injection of 20 cubic centimetres in a vein and 40 cubic centimetres subcutaneously should be tried. The only other occupants of the infectious huts are two cases of confluent small-pox, from which an Englishman and a Chinaman are convalescing, both having been landed from homeward bound ships. The only other place where plague is present in Egypt is El Toukh in Lower Egypt and there are only about six cases under treatment.

Pilgrims at Suez.

For the last two months pilgrims on their way to Mecca have been assembling at Suez and every week steamers carry them away to Jeddah in batches varying from 300 to 1500. The old khans or caravanserais in the town are full of picturesque travellers from Syria, Turkey, the Caucasus, Turkestan, Morocco, Lake Chad, and even from Cape Town. The Moors prefer an encampment of tents on the seashore near a favourite mosque. The Cape Town pilgrims, who are perhaps the least numerous, are Mussulmans descended from the old Arab traders who have intermarried with the colonials in Cape Colony and they all talk English. One woman this year claims Irish descent. The khans are yellow-washed with lime before and after their annual occupation but they are badly ventilated and some of them smell horribly of underground cesspools which can never be deep because of the high level of the subsoil water. The women with their children lodge on the upper floor of the khans. The Egyptian contingent of pilgrims this year will number about 5000, being only half the number of last year. The present arrangements for protection from returning pilgrims are as follows. On their return journey from the holy places all pilgrims of all nationalities are stopped at Tor to undergo quarantine and disinfection according to regulations which depend upon the then state of health at Mecca. After leaving Tor the non-Egyptian pilgrims pass through the Suez Canal and are not allowed to land in Egypt. The Egyptian pilgrims, on the other hand, are visited by the male or female quarantine officers when the ship reaches Suez and if any cholera or plague be discovered on board the steamer all the passengers are sent back to Tor. If the ship be passed as healthy she moors alongside the pilgrim wharf specially set apart for this purpose and divided off by barriers from the rest of the quay and the pilgrims are allowed to land one by one, their passports are examined and their addresses are taken, and the list is forwarded to the sanitary inspector of the district to which they are going. As a second line of defence every pilgrim is then individually seen by Dr. Creswell, the medical officer of the port, who allows the obviously healthy to proceed without delay but keeps all the doubtful under observation for a thorough examination. After a detailed examination each man is either passed as healthy or is transferred to the isolation hospital where his disease is thoroughly investigated. This is the only way of knowing whether a returning pilgrim is suffering from diarrhœa, dysentery, or cholera, or whether his fever is due to plague or to malaria, his enlarged glands to tubercle or to plague, and his pneumonia to influenza, to plague, or to the relatively innocent pneumococcus.

Cairo, Jan. 9th.

NEW YORK.

(From our own Correspondent.)

Report of the Surgeon-General of the Public Health and Marine Hospital Service of the United States for 1904.

This report, which has just been issued, states that at the close of the fiscal year 1904 the commissioned corps of the service consisted of 118 officers as follows: the surgeon-general, six assistant surgeons-general, 25 surgeons, 36 passed assistant surgeons, and 50 assistant surgeons. During the fiscal year 840,714 immigrants were inspected by officers of the service to determine their physical fitness for admission as prescribed by the immigration laws. By far the greater number of these were landed at New York, and of 633,811 who arrived at that port 1368 were deported, 756 of these being sent back suffering from trachoma. Boston received 80,017 immigrants 106 of whom were deported. The immigration to Baltimore was 56,371 of whom 98 were deported. Acting Assistant Surgeon Safford of Boston says in his report that there seems to be a decided increase in the physically and mentally defective immigrants from Great Britain and Ireland. The report of the division of sanitary reports and statistics shows a total of 25,106 cases of small-pox in the United States for the fiscal year 1904. The total for the previous fiscal year, 1903, was 42,590 cases, so that the numbers for 1904 are a very substantial decrease. The surgeon-general recommends the establishment of a leprosarium in the continental United States. Plague, which has existed in San Francisco since March, 1900, though reported occasionally during 1904, has steadily diminished. The current number of the report contains 640 pages of reading matter and is replete with valuable information and statistics relating to public health. It contains, moreover, several original papers of much scientific and medical interest contributed by officers of the service. The volume reflects great credit upon Surgeon-General Walter Wyman and the officers of the service.

Poisoning by Wood Alcohol.

The fatalities which have occurred recently in Russia as a result of poisoning by wood alcohol have again attracted the attention of the medical profession of the United States. Until about a year ago the methyl alcohol in use in Russia was too repugnant to taste and smell to be used as a beverage. In the early part of 1904, however, "purified" deodorised wood alcohol, known in the United States under the name of "Columbian spirits," was introduced into Russia, since which time 35 cases of blindness and death from the internal use of wood alcohol have been recorded. As in the United States, methyl alcohol has been used in Russia in the manufacture of beverages and internal remedies. When more than 20 persons died in New York some few months ago from drinking spirits adulterated with wood alcohol the public were thoroughly aroused and the newspapers clamoured for legislative action but the circumstances now seem to be almost forgotten.

The Atmosphere of the New York Subway.

Owing to the agitation in the lay journals with regard to the impure condition of the air of the New York subway Professor Chandler was called in to make an investigation into the matter. His report states that the air of this partially underground railway is, considering the circumstances, remarkably free from impurities and that statements to the contrary rest on no sound foundation. Notwithstanding this expert opinion a feeling still exists in the minds of many that there is room for improvement in the conditions prevailing in the subway. At a meeting of the advisory board of the New York health department held on Dec. 13th, 1904, many members expressed the opinion that the present stone roadbed was unsuitable and that to render the air pure a new roadbed should be made. This should be smooth so as to permit of sweeping and thorough cleansing, an impossible task under existing conditions.

Jan. 9th.

AUSTRALIA.

(From our own Correspondent.)

Infectious Disease in Victoria.

The return of infectious diseases for the last fortnight, presented at the last meeting of the Board of Public Health of Victoria, showed the following comparison between the corresponding periods of last year and this. Typhoid fever: for the State—1903, 16 cases, 2 deaths; 1904, 19 cases, 1 death; for the metropolitan area—1903, 8 cases, 1 death; 1904, 9 cases, no deaths. Diphtheria: for the State—1903, 30 cases, 4 deaths; 1904, 78 cases, 5 deaths; for the metropolitan area—1903, 19 cases, 3 deaths; 1904, 31 cases, no deaths. Scarlet fever: for the State—1903, 47 cases, 1 death; 1904, 21 cases, no deaths; for the metropolitan area—1903, 35 cases, 1 death; 1904, 10 cases, no deaths. A Bill is now before the State Parliament dealing with the Queen Victoria Infectious Diseases Hospital. Its object is to compel all the municipalities concerned to contribute to its maintenance. Since Oct. 1st, when the hospital was opened, 63 patients have been admitted.

Prevention of Tuberculosis.

A deputation from the local branch of the National

Association for the Prevention of Consumption recently waited on the Chief Secretary of New South Wales to ask for assist[illegible] ple a knowledge of the b[illegible] ease of the disease. The [illegible] to print 100,000 leaflets and to allow these to be distributed in the institutions under Government control. The Government was further asked to establish a hospital for incurable cases of consumption. The Minister replied that the Government printing was not under his department. He could see no objection to the distribution of the leaflets as desired. The establishment of a hospital for incurable cases seemed reasonable; he could not promise, however, that the Government would erect it but the matter would receive consideration. Another deputation, from the Queen Victoria Homes for Consumptives, also asked the Chief Secretary for an increased subsidy. It was stated that in the year 1898 the subscriptions to the homes totalled £834 and in 1899 they amounted to £643 and no subsidy was received in either of those years. In 1901 the subscriptions were £658 and the subsidy amounted to £600; in 1902 the subscriptions were £978 and the subsidy was £804; and in 1903 the subscriptions reached £1455, with a subsidy of £1000. The bare cost of maintaining the homes last year was £4000, so that the committee had been compelled to encroach on the capital fund. It was asked that this year the sum of £2000 at least should be placed upon the Estimates to be available for the homes on the £ for £ basis. The committee had already received £1700 this year in subscriptions. Next year there would be about 22 extra beds available at Wentworth Falls Sanatorium, which would mean an increase of £1100 per annum in the expenditure. The committee was doing a work which would otherwise have to be carried on by the Government, since it was the consumptive poor for whom it was providing. Last year 113 patients were received at the Thirlmere Home and 50 at Wentworth Falls. The committee had received no money from the Government towards its building fund and had received nothing from the Government for pauper patients. The Chief Secretary said that he recognised the noble work which the homes were doing and he was also impressed with its importance from an economic aspect. He understood that £1000 were already placed on the Estimates and he could not say without consultation with his colleagues what the Government was prepared to do about providing an additional £1000. He would, however, make a recommendation to the Cabinet on the matter. —The Kronheimer wing for consumption at the Austin Hospital, Melbourne, is in a peculiar position. Ever since the committee of the Austin Hospital decided to accept Mr. Kronheimer's gift and to erect the building, the municipal authorities at Heidelberg have strenuously protested against the proposal, and the successive Ministers of Health have been interviewed and have stated their antagonism to the proposal. In spite of this the committee has gone on with the building. Now it is finished, but it cannot be opened for patients until authority is given by the Board of Health. Under the powers of the Health Act the Minister of Health can supersede the board and in this case did so, refusing to sanction the building, and when application was made to the board for formal permission to open the board referred the committee to the Minister. The committee waited on the Minister and asked him to sanction the opening but so far he has not acceded to the request.—At the last meeting of the committee of the Victorian Homes for the Aged and Infirm a letter was read from the chairman of the Board of Health asking whether the committee would take under control buildings to be erected by the Government close to the committee's institution for the treatment of consumption. After some discussion it was decided that the committee would accept the management of the proposed consumption hospital provided the financial arrangements were satisfactory.

Hospital Affairs.

The new wards at the Stawell Hospital were formally opened on Nov. 25th, 1904, by Sir John Forrest. He said that the wards had been built and fitted with the most modern requirements by Mrs. W. H. Syme as a memorial of her late husband, Dr. Syme, whose long and valuable services to the hospital and to Stawell well deserved so fitting a memorial. He felt sure that the people of Stawell would never forget the work of Dr. Syme and that his memory and that of his wife, who had erected such splendid buildings, would always remain green.—Dr. John Williams has resigned his position as physician to the Melbourne Hospital. In recognition of his long services, extending over 30 years, the committee appointed him consulting physician. Dr. W. R. Boyd, senior physician to out-patients, was appointed physician to in-patients in place of Dr. Williams. Dr. J. Johnston was appointed honorary anæsthetist in place of Dr. L. J. Balfour, resigned.

Medical Examination of Pilots.

The Marine Board of Victoria has adopted regulations for the pilot service which will come into force as soon as gazetted. They provide that subsequently to the nomination of a candidate for a vacancy he shall be examined by a medical practitioner nominated by the Board and certified to be qualified, mentally and physically, to perform the duties of a pilot [illegible] tified [illegible] the st[illegible] or after the coming into force of the regulations, until he attains the full age of 50 years, shall be examined and passed by a medical practitioner to be approved by the Marine Board as physically and mentally fit to continue to perform his duties as a pilot at intervals of not more than 24 calendar months and after having attained that age until he attains the full age of 60 years, at intervals of not more than 12 calendar months, and in the case of a pilot who under the [illegible] he age of 60 years, [illegible] at intervals of not [illegible] lot until he arrives [illegible] before or after the [illegible] at intervals of not [illegible] the case of a pilot who under the regulations does not necessarily retire at the age of 60 years, after he attains that age at intervals of not more than six calendar months, shall have his eyes examined [illegible] ibed stand- [illegible] the Marine [illegible] testing of a pilot or of his eyesight or vision any defect is discovered which in the opinion of the medical examiner may within a variable time render the pilot unfit for service, such pilot shall submit himself for re-examination within lesser intervals. Re-examination in case of casualty and examination after absence from duty are provided for. It is further stated that [illegible] the coming into [illegible] s a pilot shall [illegible] years. In the [illegible] ge of 65 years the sufficiency of any licence held by him after he attains the full age of 60 years, whether before or after the coming into operation of these regulations, is conditional upon his presenting himself from time to time before the Marine Board when required and being permitted by the Marine Board to continue on service. Such permission shall not relieve the pilot from satisfying the requirements of the [illegible] as regards examination at the prescribed in- [illegible] may be examined into by a special board of three examiners, members of the medical profession. Every applicant for appointment as a pilot must be quite free from any sign of organic disease or degeneration, and be in general up to the first-class standard of health required by an insurance society of good standing.

Civil Ambulance Corps.

The annual report of the Civil Ambulance and Transport Corps of the St. John Ambulance Brigade, presented to the annual meeting, stated that 1605 cases had been attended to, the distance travelled being 6207½ miles. The total number of cases taken to the hospitals was 1100. Of these 469 were conveyed to the Sydney Hospital, 271 to the Royal Prince Alfred Hospital, and 106 to private institutions. From the inception of the brigade 14,774 persons have received the benefit of its services. After the amalgamation the headquarters, Balmain, and Newtown ladies' branches formed themselves into a nursing division and had been of great assistance to the corps. Notwithstanding that every effort had been made to minimise the expenditure the accounts for the eight months showed a deficiency of £114 6*s.* 2*d.* It was very necessary that the funds should be largely augmented during the current year if the corps was to maintain its proper standard of efficiency and usefulness. The staff had ably maintained its reputation for energy and attention to duty.

The Supply of Medical Practitioners in Victoria.

The annual report of the University of Melbourne for the year 1903–04 shows that the number of medical students attending lectures is 251.

Medical Man charged with Perjury.

An extraordinary charge has been partly investigated by the St. Kilda bench of magistrates. Mr. Paris Nesbit, K.C., of South Australia, a well-known but eccentric barrister who has been more than once committed to a lunatic asylum, charged Dr. R. E. Schlesinger with perjury when giving evidence that Mr. Nesbit was a lunatic in the year 1885. In consequence of the certificates of Dr. Schlesinger and Dr. Simmonds, since dead, Mr. Nesbit was committed to an asylum and detained there from April 29th to July 29th, 1885. He now alleges that Dr. Schlesinger's statements were false. He called several lay witnesses, including the Chief Justice, to say that they thought him sane at the time he was committed. He then asked for an adjournment which was granted.

Death of Dr. D. A. Gresswell.

The State of Victoria has suffered an incalculable loss by the death of Dr. Dan Astley Gresswell, chairman of the Board of Public Health. He was unquestionably one of the most capable officers who ever administered an important department. He had a most comprehensive and detailed knowledge of everything pertaining to hygiene and public health; he worked indefatigably in the administration of his department; scrupulous and firm, but always courteous, he soon earned and held the esteem and respect of the whole community. He set before him an extremely high ideal of public duty and strove to realise it with extraordinary energy and enthusiasm. Dr. Gresswell was born on Sept. 11th, 1853, at Louth, Lincolnshire. He was one of the 12 sons of Mr. Dan Gresswell, a veterinary surgeon, who was widely known for his skill and scientific attainments and who did much to raise veterinary medicine to a higher and more scientific level. Dr. Gresswell was educated at Oxford, where he took his M.A. and M.D. degrees, his medical studies being carried on at St. Bartholomew's Hospital and School. He had a brilliant career at college, gaining the Radcliffe Travelling Fellowship. His thesis on the natural history of scarlet fever attracted considerable attention and is recognised as the authoritative work on the subject. He early turned his attention to hygiene and public health and obtained an appointment as assistant inspector of the Local Government Board. He was recommended by Sir Richard Thorne for the post of medical inspector of the new board of public health of Victoria and was appointed to that post in 1890, commencing duty on March 25th of that year. He immediately made exhaustive inquiries into the sanitary condition of Melbourne and of Victoria and made numerous recommendations which, though causing many protests from vested interests, have been practically carried into effect. He was really the author of numerous legislative measures, notably on food adulteration, meat supervision, and milk supervision, and spread broadcast through the State numerous wall sheets and papers on the prevention of influenza, typhoid fever, and other infectious and epidemic diseases. In 1894 he was appointed chairman as well as medical inspector of the board. He worked persistently and, in face of much opposition, with steadfast courage and tact to improve the health of Victoria and to keep the State free from outbreaks of epidemic and infectious disease, and his efforts must have saved the community thousands of pounds. It was almost entirely due to his efforts that Victoria escaped the plague which played such havoc in the neighbouring states. He took a warm interest in the profession and was president of the Medical Society of Victoria and of the Victorian branch of the British Medical Association. Dr. Gresswell's health began to fail in November, 1898, when he had an attack of septic cholangitis which kept him from work till May, 1899. He seemed fairly well until last February when he had a similar and severe attack. He resumed duty in May but was obviously weak. On Nov. 23rd he was again attacked and gradually got weaker and died on Dec. 11th. The funeral was attended by a large number of prominent men, including the Premier, the Chief Secretary, a representative of the Governor, representatives of the medical societies and various public bodies, and many leading medical men. He leaves a widow but no children.

Death of Dr. W. Finlay.

Dr. William Finlay, formerly of Balmain, New South Wales, died recently at Bowenfels, where he had gone to recruit his failing health.

Dec. 5th, 1904.

Obituary.

THOMAS WOODS, M.D. GLASG., L.R.C.S. IREL., M.R.C.S. ENG., L.A.H. DUB., L.M. DUB.

Dr. Thomas Woods, who died on Jan. 5th at Birr (or Parsonstown), King's Co., Ireland, graduated in 1839 and attained a great reputation as a general practitioner and was held in the highest esteem by the medical profession and the public. At the time of his death Dr. Woods was in the ninetieth year of his age. He was the author of "Phthisis," "Lord Rosse's Telescope," and "Reasons against the Theory of Evolution," and contributed numerous articles to the medical and scientific journals. His series of papers which appeared in the *Philosophical Magazine* in 1852 on the "Heat of Chemical Combinations" caused considerable stir in the scientific world and contributed to the foundation of "thermo-chemistry." He was also interested in photography since the time it was in its infancy and did much to advance the art to the perfection to which it has at present attained. He enjoyed for a long time a large and lucrative practice and held up to the present year all the principal Poor-law and other appointments in the town. From a personal point of view he presented the character of the philanthropist. He was always willing to help the sick and needy and was unwearied in performing deeds of mercy with no thought for his own individual advantage, while his manner of living was quite simple. He was twice married and leaves a large family to deplore their loss. Four of his sons are in the medical profession.

DAVID MITCHELL ARTHUR, M.B., C.M. ABERD., J.P.

THE announcement of the unexpected death of Dr. D. M. Arthur of Cults, Aberdeenshire, which took place on Jan. 9th, was received throughout the district with general regret and he will be deeply mourned by the whole community among which he had laboured for over 20 years. Until about the end of 1904 Dr. Arthur was assiduously engaged in professional duty and only his more intimate personal friends were aware of his illness. He was the third son of the late Rev. David Findlay Arthur, for 50 years Free Church minister of Banchory-Devenick. After the completion of his medical curriculum he graduated at Marischal College, Aberdeen, in 1880 and proceeded to Ceylon where he practised for about two years but his health breaking down he returned to Scotland and started the practice of his profession in Cults. He applied himself with zeal and success to his work, winning in a high degree the confidence of his patients and the esteem and affection of a wide circle of friends. Several years ago he was made a justice of the peace and he held several public appointments the duties of which he discharged with scrupulous fidelity. He was medical officer of the parishes of Peterculter and Maryculter and for the County Hospital at Summerfield, in conjunction with Dr. D. Maver. Dr. Arthur, who was unmarried, is survived by a sister and two brothers, one of the latter being Dr. Alexander T. Arthur of Cults. The deceased gentleman was in his fifty-first year.

JOHN FRASER, M.B., C.M. ABERD.

THE death took place on Jan. 9th, at Pitchaish House, Ballindalloch, of Dr. John Fraser, youngest and last surviving son of Mr. Hector Fraser of Aberdeen. Dr. Fraser graduated as M.B., C.M. at the University of Aberdeen in 1903 and after acting as a locum-tenent in Preston he went, about a fortnight ago, to Ballindalloch in a similar capacity, where he contracted a severe cold which developed into pneumonia. Dr. Fraser was very popular with his patients His death is all the more sad from the fact that his brother, Mr Hector Fraser, died in May last

MEDICAL MEN CALLED TO THE BAR —We note the two following names of medical men who have passed the final bar examinations E Hugh Snell, M D, B Sc Lond, D P H Cantab, F R S Edin, medical officer of health of the city of Coventry and a member of the Middle Temple, and W Alfred Brend, M B, B Sc Lond, M A Cantab, who is a member of the Inner Temple

PRESENTATION TO A MEDICAL MAN —Dr Ernest W White, who has just retired from the medical superintendency of the City of London Asylum, Dartford, after nearly 18 years' tenure of office was the recipient of an illuminated address and a silver tea and coffee service from the members of the visiting committee (past and present) at a dinner given on Jan 11th by its chairman, Sir George Wyatt Truscott, who, in making the presentation, alluded in felicitous terms to Dr White's faithful and distinguished services to the Corporation of London On Jan 13th Dr. White was also presented by the staff of the asylum with a silver mounted tantalus as a mark of esteem and regard

FIFTH RUSSIAN SURGICAL CONGRESS — On Jan 10th the Fifth Congress of Russian Surgeons was opened in Moscow with little ostentation by a speech by one of the veterans of Russian surgery, Professor Rein, who had to deplore the thinning of the ranks of the members of the Congress, on the one hand, by the direct demands of the army in the Far East and on the other hand, by the consequently enormous increase in calls on the attention of those who remain in Russia Three notable deaths had to be recorded —viz, those of A A Bobroff, N V Sklifosovski, and K. Ph Klein, the second of whom, Sklifosovski, said the speaker 'we had begun to place after the great N I. Pirogoff' The attendance numbered about 100 The president chosen for the Congress was Professor M S Subbotin of the St Petersburg Military Medical Academy

COMPLIMENTARY DINNER TO MR PRIESTLEY SMITH —Mr Priestley Smith's recent resignation of the post of honorary ophthalmic surgeon to the Queen's Hospital, Birmingham was made the occasion of a very interesting gathering on Jan 14th, when his past house surgeons entertained their former chief at a dinner in the Grand Hotel Birmingham Dr C E Purslow presided and Mr Wilfrid Allport acted as vice president and secretary Mr Allport in proposing "The Guest of the Evening," briefly alluded to the work which had made Mr Priestley Smith's name so well known, to his great powers as a teacher, and to that unfailing sympathy and kindly help in all their difficulties which ever won for him the love and admiration of all those with whom he was associated The toast which was drunk with musical honours, was received with great enthusiasm Dr Purslow, before proceeding to make the presentation spoke of the unanimity with which the idea of the dinner and the presentation had been taken up He pointed out that of 43 residents who had served under Mr Priestley Smith during his long tenure of office it was only possible to circularise 36, since two were deceased and five were abroad, thousands of miles away, and would not have had time to reply Dr S Barwise in supporting, spoke of Mr Priestley Smith's kindliness of nature and the influence for good that he had always exerted on those with whom he came in contact, citing instances showing his uniform consideration for the patients and all those around him Dr Purslow then presented a silver rose bowl (of the loving-cup pattern) and a pair of massive silver candle sticks The bowl bore the following inscription "Presented to Priestley Smith Esq, M B Ch M, F R C S Eng, by his past house
oken of
" Mr
edings,
Priestley Smith,
in a characteristic speech warmly expressed his thanks for

the honour that had been shown him and for the presentation, which, he said, would ever be for himself and his family a pleasurable memento of the occasion.

Literary Intelligence.—Messrs. P. S. King and Son will shortly publish a book on "Infantile Mortality and Infants' Milk Depôts," by Dr. G. F. McCleary, the medical officer of health of Battersea, in which district a municipal milk depôt has been engaged in feeding babies for over two years. The importance of improper feeding as a factor in infantile mortality is, it is stated, fully explained in the work and an account is given of the history and practical working of the infants' milk depôts in this country and in America, and of the similar institutions—the "Consultations de Nourrissons" and "Gouttes de Lait"—in France. Full particulars are given as to the cost of the various appliances necessary for the work of a milk depôt, which should be helpful to members of the medical profession and of local authorities who wish for information on the subject. The book is illustrated.

Westminster General Dispensary. — This institution, which was founded in 1774 and is lodged in 9, Gerrard-street, has recently been renovated and brought up to date through the generosity of the treasurer, Mr. J. F. Blackwell. The house, which still bears marks of its having been one of the old Soho mansions, has been admirably adjusted for its present purposes. A new heating apparatus has been put in, the resident medical officer's quarters have been provided with a bath-room, electric light has been installed, and the floors in the rooms set aside for the reception of patients have been laid in marble mosaic. This, of course, makes cleanliness a far easier matter to obtain than in the days when the old-fashioned ordinary planking was used. The staff consists of two consulting surgeons, one consulting physician, three visiting physicians, three visiting surgeons, a dental surgeon, and a resident medical officer. The institution does good work in a quarter which is now very poor, though about 160 years ago it was one of the most fashionable parts of London.

Society for the Relief of Widows and Orphans of Medical Men.—A quarterly court of the directors of this society was held at 11, Chandos-street, London, W., on Jan. 11th, Mr. Christopher Heath, the President, being in the chair. The President announced the death on Jan. 5th of Mr. J. B. Blackett, who had filled the office of secretary to the society for 37 years, and the following motion was carried unanimously:—

> That this court has received with deep regret the announcement of the death of Mr. Joseph Blackett, M.R.C.S., who has so ably filled the office of secretary to the Society for the Relief of Widows and Orphans of Medical Men since 1868. The court desires to place on record its appreciation of the valuable services of Mr. Blackett to the society and of his unvarying kindness to, and consideration for, the annuitants of the charity, and wishes to convey to his family its sincere sympathy in their bereavement.

52 widows and 16 orphans had received a Christmas present, amounting in all to £574, in addition to their annuities. A sum of £1293 was allotted in payment of the half-yearly grants to the annuitants. Four new members were elected and one new application on behalf of a widow was received. Four applications for the vacant office of secretary were received and considered and Mr. Edward J. Blackett, M.R.C.S., L.R.C.P., was elected to succeed his father as secretary.

American Mosquito Extermination Society.—The second annual convention of the American Mosquito Extermination Society was held in New York and in Brooklyn on Dec. 15th and 16th, 1904. According to the report of the proceedings given in the *Scientific American* of Dec. 31st, the opening meeting was held at the New York Aquarium, where the process of mosquito hatching was shown by living examples and Mr. Frank Moss read a paper containing suggestions as to the adoption of uniform State laws pertaining to mosquito extermination. At the evening meeting two papers were read, one by Colonel W. C. Gorgas, M.D., on the Sanitation of the Panama Canal Zone so far as Mosquito Extermination relates to it; and the other by Dr. E. Porter Felt, New York State entomologist, on Diversities among New York Mosquitoes. On Dec. 16th the following papers were read or demonstrations given: by Dr. Walter Wyman, surgeon-general, and Dr. J. M. Roseneau, director of the United States Hygienic Laboratory, Washington, on the Methods of Examination and Dissection of Mosquitoes for Parasites; by Dr. Thomas Darlington, health commissioner, on Mosquito Extermination in New York City; and by Dr. Quitman Kohnke, president of the New Orleans Board of Health, on the Methods of Transmission of Yellow Fever by Mosquitoes and on the Non-infectiveness of Yellow Fever apart from Mosquitoes.

The Leeds Triennial Musical Festival.—Most of the medical charities of Leeds are interested in the success of the Triennial Musical Festival, for the committee is in the habit, after making provision for an adequate reserve fund, of distributing the profits among them in certain proportions. The first festival was held in 1858; since the year 1874 they have been held every three years, and as a result of 12 festivals a sum of upwards of £20,000 has been allotted to the charities. Great though the musical success of the 1904 festival was the financial results have been disappointing, for the profits amount only to £300. This is attributed to the period of depression in trade which has affected directly or indirectly all classes of the community. After much discussion by the committee it was agreed to distribute the sum of £1000 among the charities by drawing for the first time on the reserve fund which would then remain at £4000. This decision has met with general approval. Every one admits that the primary object of the festival is musical, but there are many who are influenced to become subscribers by their interest in the charities of Leeds. The money has been distributed as follows:—General Infirmary, £560; Leeds Public Dispensary, £120; Hospital for Women and Children, £120; and £40 to each of the following—viz.: District Nurses' Association, Blind Institution, Tuberculosis Association, Cookridge Convalescent Home, and Workpeople's Convalescent Homes.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Close, Napier, L.R.C.S. Irel., L.R.C.P. Edin., has been appointed Medical Examiner for Recruits for the West Somerset Imperial Yeomanry, at Chard.

Hodgson, H., M.B., M.S Lond., has been appointed Certifying Surgeon under the Factory Act for the Alresford District of the county of Hants.

Scott, C. R., M.B., C.M. Edin., has been appointed Certifying Surgeon under the Factory Act for the Abingdon District of the county of Berks.

Snell, E. H., M.D., B.Sc. Lond., D.P.H., has been appointed Honorary Sanitary Officer to the Coventry and Warwickshire Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bolton Infirmary and Dispensary.—Junior House Surgeon. Salary £100 per annum, with apartments, board, and attendance.

Central London Throat and Ear Hospital, Gray's Inn-road, W.C.—Honorary Second Assistant Anæsthetist.

Chesterfield and North Derbyshire Hospital and Dispensary.—Honorary Ophthalmic Surgeon.

Chester General Infirmary.—House Surgeon. Salary £100 per annum, with residence and maintenance.

County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary £150 per annum, increasing to £350, with apartments, board, attendance, and washing.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Pathologist and Registrar. Honorarium £100 per annum.

Eccles and Patricroft Hospital.—House Surgeon, unmarried. Salary £70 per annum, with board and washing.

Farringdon Dispensary and General Lying-in Charity, 17, Bartlett's Buildings, Holborn-circus, E.C.—Honorary Dental Surgeon.

Halesworth, Patrick Stead Hospital.—Surgeon. Salary £50 guineas a year.

Hospital for Epilepsy and Paralysis and other Diseases of the Nervous System.—Resident Medical Officer for six months Salary at rate of £50 a year, with board and washing.

Hospital for Sick Children, Great Ormond-street, London, W.C.—Assistant Physician. Also Assistant Casualty Medical Officer, unmarried, for six months. Salary £20, with board and residence.

Huddersfield Infirmary.—One Physician, Two Surgeons, and One Ophthalmic and Aural Surgeon (all honorary).

Notes, Short Comments, and Answers to Correspondents.

MALADVERTISEMENT.

Our attention has been called to an advertisement in various newspapers of the articles issued by the Capsuloid Company of 31, Snow-hill, London, E C. The advertisement implies, and we must believe it is intended to imply, that The Lancet has recommended the wares of the [illegible] turn [illegible] sort, [illegible] attributed to us will cause the advertisers to refrain from their incorrect statements or some papers from printing such statements in return for cash. We noticed favourably certain capsuloids manufactured by this company as a method of administering iron. It would seem that the proprietors of the Capsuloid Company having assumed for trade purposes that iron well administered prevents hair from falling out or turning grey consider themselves justified in publishing or at any rate hinting that The Lancet has recommended capsuloids for this purpose. We do not think highly of the morality or manners of such tactics.

TWO QUERIES CONCERNING TOBACCO.

To the Editors of The Lancet.

Sirs,—Perhaps the following information will interest your readers. *"H. D." asks for "anti-nicotine tobacco." If such a preparation* existed it would be useless and would have to be made up with flavouring which is most undesirable—the lighter the tobacco the less nicotine generally

Dr. James Savege asks the "effect of snuff on the heart." In the course of my association with tobacco, about 25 years, I have known men all this time, every working day, to be inhaling tobacco dust or fumes produced in the process of manufacture Uninterrupted good health is the general rule of all persons engaged in tobacco proceedings of every kind and generally of large consumers. It would be very interesting to know how often persons suffering from any trouble of upper air surfaces use snuff. Since snuff has almost gone out of use influenza, catarrh, and other troubles seem to have increased and the pernicious cigarette.

I am, Sirs, yours faithfully,

St. Leonards on Sea, Jan. 17th, 1905. F. V. Chalmers.

PS —Since the last Budget the mid-rib of the tobacco leaf has largely increased; this is [illegible] cent. of "wood" [illegible] that his "tobacco [illegible] and every essence [illegible] good tobacco.

To the Editors of The Lancet.

Sirs,—A brand of tobacco named "Timco Flake," sold by J. P. Burns, 17, South Exchange-place, Glasgow, is said to have all nicotine extracted and I have smoked it without feeling the usual effect of tobacco

I am, Sirs, yours faithfully,

Jan. 16th, 1905. P. C. S.

THE CHOICE OF AN ANÆSTHETIC.

To the Editors of The Lancet.

Sirs,—I should be greatly obliged if some of your numerous readers would advise me as to the best and safest anæsthetic to use in minor operations on children (nævi, circumcision, &c.), three or four months and two or three years old respectively, in cold weather in country cottages; also whether Junker's inhaler for chloroform is suitable and safe for young children.

I am, Sirs, yours faithfully,

Jan. 17th, 1905. Hector.

WANTED—DIAGNOSIS AND TREATMENT.

To the Editors of The Lancet.

Sirs,—I shall be glad if any of your readers can help me in the diagnosis and treatment of the case whose history follows For two or three years a young girl has been attending at my surgery at intervals of two or three months suffering from little septic wounds of the fingers and hands. Unless incised these rapidly advance in the *ordinary manner*, causing a certain amount of cellulitis. The girl's father is a grocer and she takes an active part in the shop, handling more especially cheese and bacon. In all other respects she is a very healthy girl. No other part of her body is ever affected and no other member of the family presents the symptoms. What is the cause of these sores?

I am, Sirs, yours faithfully,

Jan. 16th, 1905. J. Marsh, M.B. Edin.

A WIND PRESSURE SIGNAL FOR THE PREVENTION OF RAILWAY ACCIDENTS.

In this country it is extremely rare for a railway train to be derailed by the force of the wind but such an occurrence has happened and as recently as 1903, when it will be remembered that during the great gale of Feb. 27th of that year a mail train was blown over on Levens Viaduct, on the Furness line, and almost fell into the sea.

According to our contemporary the *Yorkshire Post*, the Furness Railway Company, in order to prevent similar accidents, has now erected an ingenious instrument which will automatically warn the signalmen on duty at Cark and Plumpton when there is unusual wind pressure of sufficient force to be dangerous to trains crossing the viaduct. The apparatus consists of a combined wind-pressure gauge and recorder and is connected with an electric arrangement by means of which bells are set in motion at distant signal-cabins. These bells will continue to ring so long as the velocity of the wind on the viaduct is dangerous to passing trains, consequently all traffic will be stopped until the wind pressure falls below the point of danger.

PLANS FOR AN ASYLUM.

To the Editors of THE LANCET.

SIRS,—Can you or any of your readers tell me where I can see or procure rough plans and specifications for a small asylum for the insane? I have just been appointed medical superintendent of an old asylum the buildings of which would have been considered disgraceful 50 years ago and I intend to obtain the building of a new institution if I possibly can. The asylum would have to be for at least 60 patients and the estimate should include all reasonable modern conveniences and improvements. I shall be glad of any information on the subject.

I am, Sirs, yours faithfully,

Jan. 15th, 1905. MEDICAL SUPERINTENDENT.

WOMEN AND MEALS.

IN few of the discussions on physical deterioration has it been brought prominently enough to the front how women generally, and especially housewives and mothers of families of the middle classes and of the artizan and mechanic sections, shirk the duty of preparing proper meals for themselves and their children when the husband and father is absent at business, at the shop, or "inside," to use the phrase employed by the workers in large factories. "Feed the brute" is an aphorism familiar in all classes of society but the necessity for feeding properly also his offspring and their mother does not seem to be equally apparent. There are too many husbands and fathers who could give evidence that when they have questioned their wives on the subject of dinner—the dinner, that is, of the wives and children—more often than not they have been told, "Oh, I didn't stop for any, I was too busy with washing (or cleaning, or sewing, or some other domestic duty) and did not trouble to get dinner at the proper time; then the feeling of hunger went off and I didn't want any dinner." In such circumstances, if the father inquires what the children had he will be told, "I boiled them an egg" or "They fancied a slice of bread and jam," or "They had a lump of bread pudding." This sort of thing continued from day to day cannot be the right way for women and prospective mothers to build up the strength either of themselves or their offspring, and, it should be observed, it is not through compulsion that the mother of the family has no proper dinner but simply through bad management or laziness. When the head of the family comes home to dinner he and the family have proper meals because he demands them for himself, and on such occasions he always finds that the wife and family can eat their meals properly and with relish. He may be told that it is his presence and his company which give his family their good appetites but this is only a roundabout way of stating the truth. He insures the decent dinner and the decent dinner provokes the appetite. The amount to which actual deterioration of the race exists among us has been much exaggerated, but undoubtedly the widespread evil of inattention to meals by the housewives of England is responsible for a good deal of their physical ill-health and that of their offspring. Every general practitioner knows this.

THE TITLE OF DOCTOR.

To the Editors of THE LANCET.

SIRS,—I am an M.B., B.C. Cantab., and write to ask you your opinion whether or not I have any right to style myself "Doctor" on cards, letters, door-plate, &c. I know some M.B.'s who do so but I personally believe that they have no right to the title. Strangely enough, I have some ambitious relatives who become annoyed when I request them not to address me as "Doctor." If I could show them in your esteemed journal a definite statement on this question it would be looked upon as authoritative by them.—I am, Sirs, yours faithfully,

Jan. 18th, 1905. M.B., B.C. CANTAB.

*** There is no "right," but custom sanctions a Bachelor of Medicine being addressed as "Doctor" and we follow this style in our own columns.—ED. L.

THE TREATMENT OF STRICTURE.

To the Editors of THE LANCET.

SIRS,—I have now under my care two cases of gonorrhœa treated about six weeks in the usual way, but both have a contracted urethra about one inch below the meatus; one may be a chancre. There is glandular enlargement in left groin. The other appears simple stricture; in each case the discharge has practically ceased. I shall be glad to learn what would be the best treatment in each case.

I am, Sirs, yours faithfully,

M.R.C.S., L.R.C.P.

*** Six weeks is a rather short space of time for the formation of a urethral stricture and it is possible that our correspondent's suggestion as to one case is correct—namely, that there is a chancre present. If this be so, or if there is any real suspicion that it may be so, mercury should be given in the usual way. If a true fibrous stricture has formed in the urethra, about one inch from the meatus, it may be treated by dilatation with bougies. With fuller details as to the conditions present it might be possible to make more definite suggestions for treatment.—ED. L.

LADY HOSPITAL MANAGERS.

To the Editors of THE LANCET.

SIRS,—Could you or one of your correspondents kindly tell me (1) what hospitals, besides Edinburgh and Bradford, have ladies on the managing committee, and (2) with what success?

I am, Sirs, yours faithfully,

Bath, Jan. 12th, 1905. R. DUCKWORTH.

◆

Mr. W. Somerville.—There are so many missionary societies under whom medical mission work can be undertaken that we cannot advise our correspondent as to any particular one. He might apply to the Society for the Propagation of the Gospel, the Society for Promoting Christian Knowledge, the Universities Mission to Central Africa, the Church Missionary Society, the Archbishops' Mission to the Assyrian Churches, or the Guild of St. Luke. Names and details will be found in any of the Church year books.

A. B.—We always consider it highly inadvisable that an assistan should start in practice in the town where his principal reside The circumstances alluded to—the absence of a bond and th alleged unfair treatment of the assistant—must determine th ethics of the case and lead the assistant to form his own judgment but our advice to him is to seek his fortune elsewhere.

M. H.—We do not quite understand our correspondent's question and he has not intrusted us with his name.

Rusholme will obtain all the information that he requires from the Colonial Office.

Medical Diary for the ensuing Week

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.).

TUESDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.).

WEDNESDAY (25th).—St. Bartholomew's [illegible], University College (2 P.M.), Royal Free (2 P.M.), Middle [illegible] (3 P.M.), St. Thomas's (2 P.M.), Lo [illegible] (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

THURSDAY (26th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), [illegible], Middlesex (1.30 P.M.), St. Ma [illegible] North-West London (2 P.M.), C [illegible] 2.30 P.M.), Metropolitan (2.3 [illegible] St. Mark's (2 P.M.), Samaritan [illegible] den-square, (9.30 A.M.), Guy's (1.30 P.M.).

FRIDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's [illegible] Charing Cross (3 [illegible] Mary's (2 P.M.), [illegible] M.), Gt. Northern [illegible] London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.).

SATURDAY (28th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.). St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (23rd).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8 30 P.M. Discussion on Hæmaturia (introduced by Dr. A. E. Garrod and Mr. B. Clarke).

ODONTOLOGICAL SOCIETY OF GR [illegible] square, W.).—7 P.M. Council. 8 P.M. [illegible] Mr. Parfitt: An Extreme Case of [illegible] R. D. Pedley: The Relation [illegible] Diseases.

TUESDAY (24th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover square, W.).—8.30 P.M. Mr. H. Lett: An Analysis of 99 Cases of Inoperable Carcinoma of the Breast treated by Oöphorectomy.

THERAPEUTICAL SOCIETY (Apothecaries' Hall, Blackfriars).—Papers:—Dr. Dixon: On the Action of Alcohol on the Heart.—Dr. Gimlette: On the Malay Treatment of Yaws.

THURSDAY [illegible]

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne street, Edgware road, W.).—8 P.M. Clinical Evening. Patients in attendance at 8 P.M.

FRIDAY (27th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square' W.).—8 P.M. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 to 9 P.M.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (17, Bloomsbury-square, W.C.).—3 P.M. Papers.—Prof. A. W. Crossley: Pharmaceutical Regulations in Germany.—Mr. P. H. Marsden: The Laws relating to Pharmacy in Russia.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (23rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. J. Galloway: Clinique. (Skin.) 5.15 P.M. Mr. J. Hutchinson, jun.: Fractures and Dislocations, the Additions to our Knowledge since the Introduction of X Rays (with lantern illustrations).

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. H. J. Davis: Cardiac Disease: Organic.

TUESDAY (24th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. R. Hutchison: Clinique. (Medical.) 5 15 P.M. Mr. H. B. Robinson: Cystic Affections of the Breast.

POST GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—5 P.M. Dr. S. Taylor: Treatment of Various Diseases.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.)—4 30 P.M. Dr. A. E. Giles: Endometritis and Erosion.

WEDNESDAY (25th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Collier: Clinique. (Surgical.) 5.15 P.M. Mr. E. T. Collins: Glaucoma (with lantern illustrations).

POST-GRADUATE COLLEGE (West London Hospital. Hammersmith-road, W.).—5 P.M. Mr. Armour. Tumours of the Groin.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.)—6 P.M. Demonstration:—Dr. Wylie: Naso-Pharynx.

THURSDAY (26th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical) 5.15 P.M. Mr. E. Willett: Anæsthetics.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—5 P.M. Mr. Armour Tumours of the Groin.

CHARING CROSS HOSPITAL.—4 P.M. Dr. Abercrombie: Demonstration of Medical Cases. (Post-Graduate Course.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4 30 P.M. Mr. H. W. Carson. The Present Position of [illegible]

[illegible] UMPTION AND DISEASES OF THE [illegible] P.M. Lecture: Dr. J. E. Squire. [illegible] Disease and their Significance [illegible]

FRIDAY (27th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. L. Paton: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Armour Tumours of the Groin.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

[illegible] *rate information* [illegible] *addresses of* [illegible]

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1904, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s.* carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only *affords* a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. *Advertisements* are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

A Clinical Lecture

ON

RICHTER'S HERNIA.

Delivered at St. Mary's Hospital on Dec. 15th, 1904,

BY V. WARREN LOW, M.D., B.S. LOND.,
F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS AT THE HOSPITAL.

GENTLEMEN,—I have lately had under my care in the wards of this hospital four cases of the condition known as Richter's hernia. This affection differs somewhat in its course and symptoms from the ordinary cases of strangulated hernia and its diagnosis is not always an easy matter. For this reason it is constantly overlooked in its earlier stages and in consequence its mortality is high. I am also inclined to believe that it is not so rare a condition as was previously thought, as there have been several other cases in the hospital within the last year, in addition to the four under my care. Nearly 20 years ago a certain amount of controversy waged over the name that should be given to this variety of hernia. Mr. Treves in an exhaustive paper read before the Royal Medical and Chirurgical Society in 1886[1] suggested that these partial herniæ should be called after Richter who had published a book on Hernia in 1778 (dedicated, by the way, to George III.), in which there was a chapter on what he called small herniæ, amongst which were included these partial herniæ. Mr. Treves pointed out that Littré in 1700 had described a variety of hernia in which a diverticulum, evidently that diverticulum now known as Meckel's, escaped into a hernial sac; but it was obvious that Littré had not contemplated the variety of hernia now under consideration. At the time of Treves's paper exception was [illegible] the very excellent [illegible] the name of an [illegible] d the somewhat [illegible] ggested instead. [illegible] question and it would, I think, be as difficult to avoid the term Richter's hernia as it would be to escape from a "Bell's palsy" or a pair of "Spencer Wells's forceps."

Treves's paper still remains the best summary of the facts in connexion with this condition. It is, as you all probably know, a strangulation of part only of the circumference of the gut wall, the area involved varying from a quarter, or even less, up to two-thirds or three-quarters of the circumference. It will be evident that in those cases where the larger proportion of the wall is involved the remainder of the lumen will, in all probability, be occluded by the kinking of the coil of intestine. The main facts recorded by Treves, as the result of a careful study of 53 cases, are that it is almost invariably the small intestine which is involved, generally the ileum, and that the area of gut wall strangulated is that opposite the mesenteric border. It occurs more frequently in women and in femoral herniæ; it only occurs in adults and, curiously, is more common on the right side. All four of my cases were women with right-sided femoral herniæ. The symptoms at first tend to assume a milder character than in the ordina[illegible] The vomiting is less severe [illegible] onset, and rarely feculent [illegible] the whole process of strang[illegible] and will often respond to aperients. Persistent diarrhœa has been known to exist throughout. The hernial protrusion may often escape notice and partly owing to this fact gangrene of the strangulated area is common (27 out of 53 cases collected by Treves) The mortality is therefore high. It is interesting to note, however, that cases of spontaneous cure occasionally occur with the formation of a fæcal fistula which afterwards closes of itself. The first two of these cases were published in THE LANCET of Sept. 24th, 1904, p. 895, and I will only here give a brief *résumé* of the chief points of interest.

CASE 1.—A woman, aged 30 years, was admitted to St. Mary's Hospital on Feb. 3rd, 1904. She had had a small lump in her right groin since Jan. 30th; this lump had appeared in the previous September and had then been regarded as an inflamed crural gland. It had disappeared under local treatment and there had been neither vomiting nor constipation. During the attack for which she was admitted there had been vomiting and her bowels had not been opened for three days before her arrival at the hospital. On admission she appeared ill but was not collapsed. Her temperature was normal, her pulse was 96, and her respirations were 18. There was a small tender swelling in the position of a right femoral hernia over which the skin was reddened and œdematous. There was slight distension of the abdomen but the abdominal walls were mobile and flaccid and there was only the slightest degree of tenderness. Operation showed that the hernial sac only contained pus and fæces and that the bowel had slipped back into the abdominal cavity. There was general peritonitis present, the peritoneal cavity containing fluid fæces. Near the internal opening of the femoral canal lay a coil of lower ileum of which a portion of the circumference, two-thirds, had been nipped to form a Richter's hernia. The herniated portion was gangrenous and had perforated in two places. Through a middle-line incision this coil of intestine was excised and Paul's tubes were tied into the patent ends of the intestinal canal. The patient, however, sank and died 20 hours afterwards.

CASE 2.—A woman, aged 41 years, was admitted to St. Mary's Hospital on March 5th, 1904. She had noticed a sudden pain and swelling in the right groin on Feb. 25th; she vomited at the onset of the pain. She continued to get about the house for four days before she took to her bed and was not admitted to hospital till the eighth day of her illness. Her bowels had not been opened during this period in spite of enemata and for the last four days there had been persistent vomiting. On admission her pulse was 120, her respirations were 28, and her temperature was 97° F. There was no marked evidence of collapse and the woman was cheerful. The abdominal walls were flaccid and not in the least degree tender. In the position of a right femoral hernia was a small tender swelling over which the skin was slightly reddened and œdematous. On incising this purulent fluid escaped from an empty hernial sac. Median laparotomy showed general purulent peritonitis but no fluid fæces were present in the peritoneal cavity as in the last case. A coil of lower ileum was found, of which roughly half the [illegible] herniated portion was covered with thick yellow recent lymph. The coil containing the herniated portion was fixed on the abdominal wall outside the peritoneal cavity and the latter was well flushed and drained. On the 9th the coil, which had then recovered its normal shape, was replaced in the abdominal cavity and the woman made an uneventful recovery.

In my remarks on these cases I pointed out, among other features of similarity, the insidious nature of their onset. In the first one it was only on the fourth day of the illness that the case was considered sufficiently serious to require operation, while in the second the woman got about her house for four days of her illness and it was not until the eighth day that she was brought to hospital. I would also draw your attention in the first case to the fact that in the previous September a similar attack to that for which she came to hospital was ascribed by a competent observer to inflammation of a crural gland.

CASE 3.—A woman, aged 56 years, was admitted to St. Mary's Hospital on July 30th, 1904, for "intestinal obstruction." She stated that for eight months she had suffered from some vague intestinal disturbance characterised by occasional colicky pains and flatulence with nausea. Her bowels had been irregular in their action but she said that she had not before been definitely "obstructed"; she [illegible] uring the last year [illegible] of the attack for [illegible] k previously she had been seized with abdominal pain and sickness and that these symptoms had gradually increased in severity. It was stated that before admission the vomiting had been stercoraceous in character. Her bowels had not been opened since the onset of the attack but there was not absolute obstruction and she had passed flatus up to the time of her admission. She was a spare woman who had evidently lost flesh, her tongue was dry and brown, and her breath was foul. Her

result of a special ferment. 3. It has been suggested that its production results from some loss of function of the bone marrow owing to the destruction of the latter.[23]

As regards the first hypothesis, Magnus Levy[24] states that in the case observed by him the excretion in the urine often attained 36 grammes per day. He calculated that the whole mass of the diseased red marrow could not contain more than 100 grammes. He considered, therefore, that the excreted albumose could not be derived from the bone marrow. But in Dr. Parkes Weber's case no Bence Jones albumose was found in any of the organs, and if it were due to abnormal proteid metabolism it would seem reasonable to find it in places such as the muscles and the liver, where proteid metabolism is most active. Dr. Parkes Weber found also in his case that a considerable alteration of diet maintained for two days had no effect in altering the quantity of proteid excreted in the urine. Dr. Bradshaw found, too, in one of his cases, that meals had little or no influence on the excretion of the proteid in the urine. He found that as much was excreted by night as by day, when the patient was taking meals during the day-time only, and he considered the rate of excretion to be "pretty constant throughout the 24 hours." From experiments (Stokvis) in which Bence Jones albumose was injected into the rectum and also in the veins of dogs and in which it was excreted unchanged by the kidneys it seems probable that once it is free in the blood it appears in the urine.

[illegible] D. [illegible] J. [illegible] b[illegible] They failed to find in these a body giving exactly the same reaction as those of the Bence Jones proteid in the urine. From the vertebræ and the ends of the femur, however (and in this case practically the whole of the skeleton was more or less involved [illegible] obtained a pro[illegible] Jones albumose [illegible] be obtained by employing similar methods from normal red bone marrow. They argued, therefore, that in this case at least the bone marrow was probably the seat of production of the proteid excreted in the urine. Professor Muir found in the tumour cells of the same case granules which he conjectured might be the progenitors of the Bence Jones albumose. Dr. Bradshaw and Dr. E. E. Glynn, however, made very careful examination of the tumour substance and bone marrow from Dr. Barr's case but entirely failed to find any trace of Bence Jones albumose in them. They failed also to find any trace of a ferment.

I cannot find any record of work done in support of the third hypothesis.

The blood.—Systematic examinations of the blood do not appear to have been made in many cases. Nothing beyond simple anæmia seems to have been established and in no case is it recorded that either myelocytes or nucleated red corpuscles were found.

The kidneys.—In some cases interstitial nephritis has been found. In some the kidneys were normal. The disease does not appear to have any necessary association with pathological changes in the kidneys.

DR. BARR'S CASE.

The patient, a man, aged 49 years, married, was admitted in January, 1903, into one of the surgical wards of the Liverpool Royal Infirmary. He stated that about the end of September, 1902, he began to suffer from "a bad back" which he thought to be lumbago or something similar. The pain began in the middle of the back, then extended to his side, and finally all round his body. He was treated for lumbago by his own medical attendant but, though relieved for a time, there was no permanent improvement. At the beginning of December he began to stay at home, lost flesh rapidly, and felt an increasing weakness. He was admitted to the Royal Infirmary on Jan. 10th, 1903.

On admission he gave a history of exceptionally good health, admitting no other illnesses than an ordinary cold. No history of syphilis [illegible] .ined. He stated, however, that [illegible] of winter, he and his fellow work[illegible] warming themselves by leaning their backs against a steam receiver. On one such occasion he felt a sudden severe pain in his back which incapacitated him from walking for two or three days. He remembered, too, having at times suffered some pain in the region of the kidneys. This was all he could remember of pain or sickness. His work, which had been chiefly in copper-rolling mills, had always been of the light labouring order. He had never been subjected to severe strains and had always had a good comfortable home. His appetite up to the present illness had been good. He had never been a great smoker but had chewed tobacco. He had evidently been addicted to alcohol. The family history revealed nothing of interest.

On Jan. 15th he was, at the request of the surgeon, seen [illegible] he patient [illegible] lumbago, [illegible] ial in this latter disease. The eleventh dorsal vertebra is prominent and the percussion note over it is somewhat impaired and there is tenderness on pressure. There is marked tenderness along the course of the eleventh dorsal nerve. On pressure on the head or buttocks he complains of pain shooting down his spine. There is an ill-defined fulness below the right costal margin and beneath the upper end of the right rectus muscle. A deep breath seems to catch him at the right lower ribs. The knee-jerks are considerably increased, especially the left There is no ankle clonus." On Feb. 23rd he was transferred to Dr. Barr's ward. His condition was then as follows. He was quite intelligent, his frame was wasted, his expression was listless, and his cheeks were flushed. His temperature was 98°F. There was no jaundice, cyanosis, or dropsy. His hands were pale, clear, and wasted. There were no glandular enlargements, his respiration was normal, and there was no cough. His memory and speech were quite unaffected. The patient was now unable to walk or to sit up in bed. All sensation in the lower limbs was lost, though a smart blow on the skin could be felt. Both knee-jerks were absent, as were also patellar and ankle clonus. The upper limbs were unaffected. Sensation below the level of the iliac crests was lost all round the body. There were no apparent vaso-motor or trophic disturbances, no abnormal flushing, localised pallor, sweating, or joint changes. There were no changes in the nails or the hair. The bladder and rectum reflexes were impaired and urine and fæces were passed involuntarily. The respiratory system was normal. The heart sounds were distant. The pulse was regular in time and force, 100 per minute, of low tension, and poor in volume.

[24] Deutsches Archiv für Klinische Medicin, vol. lxiii., p. 276.

On Feb. 26th a rash of a somewhat punctate red nature appeared all over the body. It was especially marked on the arms and lower extremities. By the 28th the mischief had spread in a marked degree. All reflexes below and including the epigastric had disappeared. There was a complete loss of sensation extending as high as the umbilicus. There were a marked angular curvature of the spine at the level of the eleventh and twelfth dorsal vertebræ and a fracture of the third right rib at the junction with the costal cartilage. A slight swelling could be felt over the manubrium sterni and the bone itself did not feel firm. It appeared also unusually narrow, not being much over one inch in width. The diaphragm moved but there was no movement of the recti abdominis. The vaso-motor disturbance was marked and a measly rash covered the abdomen. The pulse was soft and feeble. The appetite was poor, the bowels were confined, and the motions were offensive. The liver and the spleen appeared to be normal. The urine, which had now to be drawn off, contained three grammes per litre of albumose. On March 9th the pain in the back and the right side had increased. The bladder had to be washed out with boric lotion. On the 13th the patient's temperature was 102·8°, the pulse was 122, and the respirations were 24. Percussion over most of the lower lobe of the left lung gave a dull note. The breathing was deep but not laboured and almost entirely abdominal, the inspiration was harsh, and the expiration was prolonged. The breath had a peculiar sweet odour. The cheeks were flushed and of a slightly purplish hue. On the 14th the temperature, which had been somewhat reduced, was again 102·4°, the respirations were 28, and the pulse was 112. The urine was normal as to chlorides, deficient in phosphates, and contained no acetone or diacetic acid. On the 20th for the last few days the patient had had muscular twitchings, especially marked on passing the catheter. Control of the bladder and the rectum was now completely lost and the urine dribbled away. There was no alteration in sensation. Speech was reduced to a hoarse whisper. The tongue was dry and coated with brown crusts. The temperature was 101°, the pulse was 118, and the respirations were 22. On the 22nd the patient was worse and much troubled with hiccough. This was relieved by cajuput oil and a mustard plaster over the epigastrium. The hoarseness was more marked. On the 24th at 8.30 A.M. the patient seemed to be fairly comfortable and was not complaining. At 8.50 the house physician was called but the patient was dead on arrival. A few minutes previously he had complained of a choking sensation.

Condition of the blood.—An examination of the blood on March 9th gave the following result: xanthocytes, 4,200,000 per cubic millimetre; leucocytes, 7900 per cubic millimetre; and hæmoglobin, 80 per cent. There were no nucleated red corpuscles. The differential count of the white corpuscles

TABLE II.—REACTIONS OF PROTEIDS OCCURRING IN URINE.

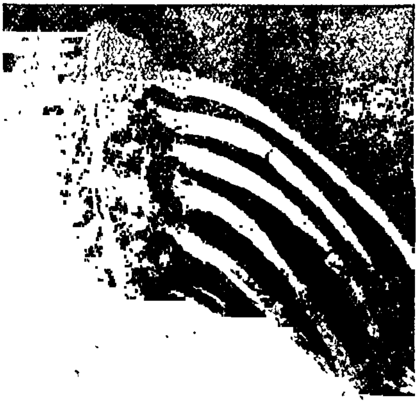
—	Heat.	Nitric acid.	Hydrochloric acid.	Potassium ferrocyanide and acetic acid.	Alcohol.	Saturation with NaCl and addition of acetic acid.	Biuret reaction.	Solubility in water.	Saturation with magnesium sulphate.
Serum albumin.	Coagulated about 73° C. Does not redissolve on boiling.	Precipitated. Does not redissolve on boiling.	Coagulated.	Coagulated:	Precipitated and coagulated.	Precipitated.	Violet colour.	Soluble.	Not precipitated.
Serum globulin.	Coagulated (in saline solution). Does not redissolve on boiling.	"	"	"	"	"	"	Insoluble.	Precipitated.
Bence Jones albumose.	Precipitated about 60° C. Redissolves on boiling; reappears on cooling (NaCl must be present and urine must be acid).	Precipitated; partially redissolved on boiling; reappears on cooling.	Ring formed at the junction of the acid and urine diluted 20 times (Bradshaw's reaction).	Very slowly precipitated. The precipitate becomes less distinct on boiling.	Precipitated.	"	"	Soluble in cold alkaline solution.	Slight flocculent precipitate.
Proto-albumose.	Soluble at all temperatures unless salt is present in sufficient quantity to precipitate it.	Precipitated. Redissolves on heating and reappears on cooling.	(?)	Precipitated. Redissolves on warming.	Soluble in 80 per cent. alcohol.	Precipitated. Redissolves on warming.	Red rose colour.	Soluble in hot and cold water and in saline solutions.	Precipitated.
Hetero-albumose.	Precipitated (in NaCl solution) at 65° C. Does not redissolve on boiling. The precipitate is soluble in dilute acid or alkali solution.	"	(?)	"	Precipitated (in neutral solution).	Opacity on heating.	"	Insoluble in hot and cold water. Soluble on addition of salt.	"
Deutero-albumose.	Not precipitated in NaCl solution or on boiling.	Not precipitated unless a considerable amount of salt is added.	(?)	"	"	Precipitated. Redissolves on warming.	"	Soluble in hot and cold water.	Not precipitated.
Peptone	Not precipitated.	Not precipitated.	Not precipitated.	Not precipitated.	Precipitated.	Not precipitated.	"	"	"

Pure Bence Jones albumose dissolved in water is entirely unaffected by heat. The effect of heat on it, when dissolved in urine, is probably due to the presence of uric acid.

was as follows: polynuclear, 82 per cent.; eosinophile polynuclear, 1 per cent.; transitional, 2 per cent.; lymphocytes, 10 per cent.; and large mononuclear, 4 per cent.

The general character of the urine throughout was as follows. About 30 ounces were passed in the 24 hours; it was orange in colour, cloudy and opaque, had a normal odour, and a specific gravity 1022. At first the reaction was acid; afterwards it was alkaline. The deposit consisted of granular casts and later of crystals of triple phosphates. The special albumose found will be discussed more fully. The urine gave the reactions in Table II.

Necropsy.—The post-mortem examination took place 27 hours after death. As regards the sternum, there were no spontaneous fractures. On sawing down the middle several small masses up to the size of a cherry-stone were found. Some were dark purple and others were greyish. The manubrium was hollowed out and contained a dark purplish mass. The sternum was very narrow. On the right side there was a line of fracture running downwards in the anterior axillary line affecting the third to the fifth ribs inclusive. The sixth, seventh, and eighth ribs were fractured in a line more posterior. The ninth, tenth, and twelfth ribs were not fractured. The eleventh rib was fractured one inch from the costal cartilage. In the fourth rib there was a loss of hard substance for about three inches and here there was a spindle-shaped tumour, of half the size of a pullet's egg, projecting into the pleura. On the left side the sixth and tenth ribs were fractured one inch from their heads. All the ribs contained small soft masses of new growth which made them extremely friable. As regards the spinal column, there was marked irregularity of the bodies between the ninth and eleventh dorsal vertebræ accompanied by some twisting, so that the tenth vertebra projected to the right side of the ninth. Some of the bodies had collapsed, so that the cancellous tissue was practically absent. The vertebræ in the lumbar region were softened The lungs were emphysematous, otherwise they were normal. The heart weighed 12 ounces. The nutrition was good and there was plenty of fat. The valves were somewhat [illegible]



Reproduction of photograph showing tumours in vertebræ and spontaneous fractures of ribs. (The specimen is in the Pathological Museum of Liverpool University.)

and rather firm. Round the large veins the colour was green, probably owing to the presence of putrefactive organisms. The spleen was rather diffluent. The cortex of the kidneys was diminished in size and studded with yellow patches of the size of a pin's head. The capsules could be readily stripped off. There was some pyelitis. The walls of the bladder were hypertrophied. The mucous membrane was injected and covered with a fleshy material. The ureters were dilated to twice the normal size.

Microscopic examination of the tumours.—I have made sections of the large soft tumour projecting from one of the ribs and also from the tumour growth in the ribs. The tissues were hardened in formalin and imbedded in paraffin. Some have been stained with hæmatoxylin and some with Mann's stain (eosin and methylene blue). The great majority of the tumour cells were of the lymphocyte type. No eosinophile cells were found. Many red blood corpuscles were to be seen in the sections but none of them appeared to be nucleated. There were some large cells containing a considerable amount of protoplasm and a reniform or double nucleus. In the large tumour projecting from the ribs there appeared to be some attempt at the formation of bone. I have not completed the microscopic examination and hope to make a further contribution on the subject.

Liverpool.

A CASE OF ENCYSTED CEREBRAL ABSCESS.

By PETER PATERSON, M.B. GLASG., M.R.C.S. ENG.,
ASSISTANT SURGEON TO THE GLASGOW ROYAL INFIRMARY.

THE following case may be of interest as it presents some unusual features.

A girl, aged five years, was admitted into the Glasgow Royal Infirmary on July 28th, 1904, with a history of having had a fit a few hours previously. There had been a slight discharge of pus from the right ear for two years before admission but with this exception she had always been healthy. The fit consisted in irregular jerkings of the face and the limbs together with unconsciousness. The convulsions came on suddenly when she was at play and, so far as could be ascertained, did not begin in any definite order. Nothing suggestive of a rigor had been observed but it is very probable that the seizure took the place of what would have been a rigor in an older subject. When brought under observation the patient was pale and had generalised convulsions, most marked on the right side. When the movements ceased, which they did about half an hour before operation, the limbs were neither in a spastic nor paralysed condition. The eyes showed conjugate deviation to the right; the conjunctival reflex was present and the pupils were equal and fixed. The discs were slightly congested. A red fluctuant swelling was present behind the right ear and pressure on this increased the convulsive movements. The right meatus contained a quantity of fœtid pus and when this had been removed it was seen that the membrane had quite disappeared, its place being occupied by a mass of granulation tissue. The temperature was 102° F., the pulse was 120, and the respirations were 28.

First operation.—Operation was performed an hour after admission, the patient being still unconscious. An incision was made behind the ear when about half an ounce of pus escaped from the abscess in this situation. The mastoid was then seen to be perforated by a small opening in the region of the masto-squamosal suture. The antrum and middle ear were next exposed. These, owing to caries, practically formed one cavity which was filled with granulation tissue. On the granulations being removed the tegmen tympani was found to be eroded with a small perforation at one point. Through this opening a bud of granulations presented. This protrusion was gently pushed aside but no pus escaped. The parts were thoroughly cleaned and packed with a mixture of iodoform and boric acid.

The patient had a quiet night and awoke in the morning conscious and with the temperature 99·4°, the pulse 130, and the respirations 26. Two days later the first sign of paralysis appeared as a paresis of the right side of the face. This disappeared after ten days, by which time also the temperature, the pulse, and the respirations were normal, whilst the condition of the optic discs was stationary. The patient remained in this condition for seven weeks, though an occasional convergent squint was present, and she complained towards the end of a constant pain in the anterior aspect of the right forearm. All the movements of the ocular muscles were normal. During the whole of this time she was clear mentally, answering questions with promptitude and intelligence. Nine weeks after the operation the temperature, the pulse, and the respirations commenced to rise, the temperature running from 1° to 2° above normal. Three days after the beginning of this elevation of temperature she suddenly had another fit of generalised convulsions and at the same time she became unconscious, the insensibility rapidly deepening into coma. During this seizure, and persisting after it had passed off, there was an internal strabismus of the right eye, but apart from this there was nothing in the movements of a localising nature. The conjunctival reflex was absent and the pupils were dilated, fixed, and equal. The temperature ran up to 104·2°, the pulse to 160, and the respirations to 30.

Second operation.—When the granulations in the wound were removed it was found that the bone had been eroded from the tegmen tympani outwards along the roof of the cavity and upwards over the side of the skull to a point one and a quarter inches above the level of the posterior root of the zygoma. The edges of this erosion had a worm-eaten appearance and the bone for some distance round the hiatus was perforated in several places. Through this opening the congested dura mater projected and this on palpation could be felt pulsating. The membranes were incised and a hollow needle was introduced into the cerebral substance. At a depth of three-quarters of an inch from the surface the instrument came into contact with a firm resisting mass. The size of the tumour was ascertained by passing the needle in various directions but steady and fairly strong pressure failed to make it penetrate the substance. A solid tumour, probably tuberculous, with lepto-meningitis was diagnosed and as the mass seemed too large and too deeply situated for removal the patient was put back to bed where she died five hours later.

Necropsy (permission was given to open the head only).—At the post-mortem examination the surface of the brain was found to be dry and somewhat flattened with congestion of the blood-vessels, whilst the base was the seat of a lepto-meningitis. Adhering to the upper surface of the petrous bone was a fluctuant tumour of about the size and shape of a hen's egg. This mass was adhering to the dura mater directly over the tegmen, the point of union not being more than a quarter of an inch in diameter. No opening could be found through which fluid could be pressed from the interior. When an incision was made into the tumour thick creamy pus escaped and nothing was left behind but the dense capsule. The inner surface of this capsule was smooth and polished-looking whilst the outside had a flocculent appearance. The abscess had occupied the temporo-sphenoidal lobe, the cerebral substance surrounding it being much softened. The ventricles were filled with turbid fluid and the right was distorted from pressure of the abscess though a layer of softened brain substance separated them. The vessels of the ventricles were congested. The sigmoid sinus was healthy. Sections of the abscess wall showed an irregular network of connective tissue with a round celled exudation and a few tubercles with giant cells A few blood vessels were present in the outer part of the wall

Judging from the thickness and density of the abscess wall it must have been present for a considerable time probably starting about the onset of the otorrhœa Striking features in the case were the toughness of the wall of the abscess, as even after it was removed considerable force was necessary before a needle could be made to penetrate it and also the absence of symptoms referable to the abscess notwithstanding that the temporo sphenoidal lobe in which it was situated was destroyed to a very considerable extent The clinical aspect pointed more to a meningeal infection

Glasgow

RESEARCHES INTO THE ETIOLOGY OF CARCINOMA ON THE PRESENCE OF PLASMODIOPHORÆ IN CARCINOMATOUS TUMOURS AND THE SUCCESSFUL CULTURE OF THE PARASITES

BY W FORD ROBERTSON, M D EDIN
PATHOLOGIST TO THE SCOTTISH ASYLUMS

AND

HENRY WADE, M B EDIN , F R C S EDIN
CONSERVATOR OF THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH

THE researches of which we wish briefly to record some of the results were undertaken specially with a view to testing the validity of the hypothesis that carcinoma is dependent upon the growth of a parasite of the same class as the plasmodiophora brassicæ which is known to cause tumour growths in various members of the cruciferæ, as well as in other plants This hypothesis has been strongly advocated in various forms by Behla Podwyssozki Roswell Park Gaylord,[1] and others, but only a certain amount of presumptive evidence has hitherto been obtained in support of it To most workers at the subject of cancer it has seemed so improbable that they have devoted themselves to entirely different lines of investigation Our own researches seem to show that it is in accord with fact We have at least succeeded in demonstrating the presence in carcinomatous tumours of bodies corresponding in form and in reaction to a special method to 14 phases in the developmental cycle of the plasmodiophora brassicæ and in growing from such tumours an organism which accurately represents several successive phases of a parasite of this class

On the threshold of the inquiry we were confronted with the difficulty already experienced by other worker of obtaining a clear view of the plasmodiophora brassicæ in vegetable tumours The ordinary staining methods were found to be useless for the purpose We devised special staining processes by which the organism was made to retain certain basic dyes but we found that when applied to carcinomatous growths they were of little value on account of the depth of the colour imparted to the tissue elements Nevertheless by these methods we were able to observe in carcinomata bodies having a very close resemblance to the plasmodiophora brassicæ and we were therefore encouraged to pursue the inquiry further It occurred to us that in a case of this kind in which ordinary staining methods had failed to yield satisfactory evidence either in support of or against the presence of a protozoan organism success might be attained by the employment of metallic processes The platinum method as used for the nervous system, was first tried and it proved to be of some utility for the purpose in view Among the other metallic methods which we tried was one of impregnating tissues with silver which had been partially worked out for the nervous system some years ago but which had been abandoned on account of certain practical difficulties it presented These difficulties were soon overcome and it was found that the method gave a better demonstration of the plasmodiophora brassicæ than any staining processes we had employed It was also found to be applicable to formalin hardened tissues from the human subject It has been chiefly by the use of this silver method and toning of the silvered sections with gold, platinum, and palladium (see appendix) that we have been able to recognise what appear to be the various stages of a plasmodiophora in carcinomatous growths as well as to identify the organism [illegible]

Plasmodiophora brass[illegible]

as found in the tumo[illegible] turnip and which are generally referred to in this country as ' finger and toe disease In America the condition is commonly known as "club root' and in Germany as "kohlhernie The plasmodiophora brassicæ was discovered by Woronin in 1876 and described by him in 1878 At this date he predicted that certain malignant growths in man would eventually prove to be due to a parasite of the same nature The various stages of the organism have also been described by Nawaschin De Bary, Gaylord and others The several descriptions that have been given do not fully harmonise with each other and a perusal of them leaves the impression that the observers have been unable owing to the difficulty that there is in s[illegible] to obtain a view of all of [illegible] With the aid of the [illegible] succeeded in tracing most of the various stages of its developmental cycle We find that this cycle is much more complicated than would appear from existing descriptions Important stages seem to have passed unobserved As will be seen the stages to which we refer are of vital importance for the investigation of the question of the presence of plasmodiophoræ in malignant tumours

From the descriptions that have been given one gathers that swarm cells having entered a root hair of the plant reach the interior of certain of the plant cells here they proliferate and stimulate the plant cells to divide, after a time several of these amœbæ lying in the protoplasm of a cell coalesce to form a plasmodium in which spores subsequently develop these spores reach the ground when the plant decays and with the advent of spring develop directly into the amœboid swarm cells, which may once more find their way into the root hairs of a young plant We have endeavoured to trace the various stages of the parasite not only during its sojourn in the vegetable host but also during its ectogenous existence which under natural conditions is passed in the ground We have found that the phenomena of this period can be studied in turnips in which the plasmodiophoræ have reached the spore stage if the roots are incubated for several weeks at a temperature of from 55° to 60° F

To follow the various phases of this organism even when it is well stained is by no means an easy matter Normal and degenerative tissue structures and granules complicate the histological pictures and give rise to many difficulties of interpretation From this cause we have in one particular at least [illegible] regard to the bodies which [illegible] We have recently found [illegible] fectly healthy turnip and notwithstanding the readiness with which on first view they seem to fit into the cycle we are forced to conclude that they have really no place in it The genuine spore is a nucleated body and the immediately succeeding stage is not granular, as we were led to believe, but the amœboid swarm cell We have also fallen into error in our former description[2] through not having had an oppo[illegible] [illegible] tumours and by hav[illegible] be completed from the [illegible] As the granular stage appeared to arise directly from a spore it seemed legitimate to infer that the amœboid swarm cell described by others represented a later stage By the use of improved methods of toning the silvered sections we have been able to trace the development of the swarm cells directly from the nucleated spore and to observe that it is from these minute amœboid bodies that the granular stage takes origin By the study of the earliest examples of kohlhernia that we could obtain[3] we have we think succeeded in tracing this stage and the immediately succeeding one on to the nucleated stage Our description of the life cycle differs from that of others mainly in the recognition of the granular and post granular stages without a knowledge

of which the question of the relation of carcinoma to plasmodiophoræ would inevitably remain obscure.

We begin with the spore which under natural conditions falls into the ground and lies dormant until early summer. It appears in silver-gold preparations of kohlhernia in turnips as a pale, round body from 1μ to 2·5μ in diameter, having a brown or black granular nucleus, measuring from 0·8μ to 1·4μ (Fig. 1, A 1). When this spore begins to germinate its nucleus undergoes some process of division which it is difficult to trace accurately. It appears to be initiated by the throwing out of a small body from the nucleus. Either two or four small dark bodies are ultimately formed (A 2). The immediately succeeding phase would appear to follow one or other of two courses, probably corresponding to a sexual differentiation. In one mode of development a pale reddish oval or pear-shaped non-nucleated body, from 1·8μ to 2·3μ in diameter, is formed (A 3). Within this there next appears an almost colourless oval central portion with well-defined margin and generally containing a minute dark particle (A 4). Then the clear central portion gradually enlarges and the dark granules within it multiply, whilst at the same time the marginal portion of the cell becomes attenuated (A 5). In the other mode of development the bodies resulting from division of the spore assume an oval form and a reddish, slightly granular appearance (A 3). More darkly stained particles, commonly four in number, soon become visible within them (A 4). There is next a gradual transformation into black granules indistinguishable from those resulting from the first mode of development. There is evidence that, prior to the development of the granules within them, both varieties of these bodies are motile. They very commonly invade the nucleus of the turnip cell and the second variety would appear also to invade the hyaline spheres which form a portion of the cell structure. They may even pass out of the vegetable cell in which they had origin. They are without doubt to be identified with the swarm cells or myxamœbæ described by others. In natural conditions they develop in the earth and having gained entrance to the root-hairs of a young plant travel by way of the vessels to various situations. Both varieties of myxamœbæ become transformed into the granular bodies which represent what we have termed the granular stage of the parasite (A 6). In silver sections toned with palladium and gold these bodies are generally deep black. The smallest of them are no larger than the most minute micrococcus. They are very frequently placed in rows of three and in these instances there is a suggestion of a delicate, unstained, uniting thread, the actual existence of which is, however, uncertain. These granules, which in natural conditions are now lying within the protoplasm of the cell of a young plant, gradually increase in size (A 7). At first they retain their dark appearance but this is gradually lost as they pass into what may be termed the post-granular phase (A 8). They now appear generally as pale reddish, almost homogeneous, round bodies with a sharply defined outline (Fig. 2). The protoplasm of the cell, which is more or less packed with parasites, becomes of a granular and opaque appearance, in consequence of which the outline of the organisms is obscured. The smallest of the parasites have at this stage a diameter of about 0·5μ, whilst the largest (A 9) equal the small forms of the next stage into which they gradually pass. This is the nucleated pre-conjugation stage. The nucleus, which is centrally placed, is at first very pale and difficult to recognise (A 10). The organisms gradually undergo a further increase in size and the nucleus becomes distinct (Fig. 3). At this stage they measure from 1μ to 3·4μ in diameter. They present at least five or six different aspects which as yet it has been impossible to arrange in any series. It seems probable that a sexual differentiation again underlies certain of these differences in appearance. The organism may be round or oval; the nucleus may be relatively large or small and occasionally a distinct nucleolus is present; and, as indicated above, the size of the organism, even when there is reason to believe that the post-granular stage has long been passed, exhibits a considerable range (A 11). There is clear evidence that the organisms divide by mitosis (Fig. 4). There is proof that the morbid proliferation of the vegetable cells is in active progress whilst the parasite is present in the granular stage only and that it may have advanced a considerable way before the nucleated pre-conjugation stage is reached. The next stage is that of the gamete (A 12). The nucleus disappears and the whole organism assumes an opaque, faintly granular aspect. All or most of the parasites in the cell undergo this transformation at the same time. Two adjacent cells then appear simply to fuse to form one (A 13). Simultaneously with this conjugation a distinct capsule forms round the zygote. The new cell has at first a finely granular, opaque appearance. Subsequently it diminishes in volume and becomes rounded in form. A remarkable alteration then occurs in consequence of which the body comes to have the appearance of four (sometimes more) round, pale globules, closely adherent to one another. Surrounded by its delicate capsule the organism has at this stage a very characteristic aspect. Very commonly several adjacent parasites appear to fuse and become enveloped by a common capsule. As, however, the final result is always the same—the formation of the peculiar bodies just described—it seems probable that there is a true fusion of only two individuals. At no stage of the process is there the formation of a multinucleated mass of protoplasm—i.e., a plasmodium. The term plasmodiophora brassicæ would therefore appear to be a misnomer. After a time the organism assumes the form of the nucleated spores already described and the cycle is completed. It will be noticed that in this cycle the large amœbæ figured by Woronin, and described also by others, have no place. It seems probable that what have been regarded as amœbæ were simply aggregations of the granules which arise in the swarm cells. Such aggregations may very commonly be seen within the vessels of the turnip at an early period of infection.

The bodies resembling plasmodiophoræ in carcinomatous tumours.—We have used for the purposes of our investigation chiefly carcinomatous tumours of the breast and malignant adenomata of the intestine (and secondarily affected abdominal glands) removed at operation. As controls we have used simple tumours and various inflammatory tissues, also removed at operation, as well as the tonsil, stomach, liver, and pancreas of the general paralytic and various nervous tissues.

The methods we have employed have been the same as those used for the study of the plasmodiophora brassicæ. It is not, however, to be thought that in these methods we have a means by which plasmodiophoræ can be specifically stained. Although they are capable of rendering such parasites visible they have the disadvantage that they at the same time colour almost everything else contained in the tissues. A partial exception is, however, to be made as regards the combined palladium and gold toning process with which we can claim to have made at least a beginning in the differential staining of certain stages of a plasmodiophora. To a greater or less extent in all the preparations the products of various pathological tissue changes, as well as some normal structures, simulate very closely many of the bodies which there are grounds for believing are plasmodiophoræ. The search for these parasites in carcinomata is therefore beset with difficulties and but for the fact that certain special structural characters can occasionally be recognised it would be impossible to derive any conclusive evidence either in support of, or against, their presence from the histological part of our investigation. There is, of course, room for difference of opinion as to the diagnostic value of any alleged special structural character. We can merely present the evidence as we have found it. The conclusions which it seems to us to warrant when taken in conjunction with that derived from cultures will be considered later.

The bodies in carcinomata, which we believe to be plasmodiophoræ, are considerably smaller than the plasmodiophora brassicæ. Both show a considerable range of size in all their stages and it is therefore somewhat difficult to estimate their average relative dimensions. Fuller investigation of the various phases of both parasites obliges us to regard the difference between them to be less than we have formerly estimated it to be. It may be stated that roughly the alleged plasmodiophoræ of carcinoma are about one-fifth of the volume of the corresponding phases of the plasmodiophora brassicæ. Bodies accurately corresponding in reaction and form to the resting spore of the plasmodiophora brassicæ may be observed, especially in palladium-gold preparations, lying between the epithelial cells, among the connective tissues, in the glandular spaces of adenomata, and occasionally within the nucleus or protoplasm of the epithelial cells. (Fig. 1, B 1.) The form of the protoplasm is not always rounded. Small dark bodies, devoid of any recognisable protoplasm, may also be observed and there are some grounds for supposing that they are really of the same nature as the nucleated bodies.

Forms representing the first phase in the transformation of the spore into myxamœbæ though rare may occasionally be seen (B 2) Bodies which may be young myxamœbæ (B 3) are common in the intracellular spaces and may occasionally be observed in the protoplasm or nucleus of the epithelial cells This phase is however one lacking in any distinctive characters The fully developed myxamœba in both its forms is represented by bodies which may occasionally be seen in the same situations (B 4) The clear oval central portion of one of these forms with its contained dark granule has a characteristic appearance which it is difficult to believe could be simulated by mere degenerative material The development of these myxamœbæ into the granules is represented more rarely (B 5) but the fully developed granules (B 6 and 7) are often present in abundance It is this stage of the organism which, both in kohlhernia and in carcinoma we have found to be in a measure specifically stained by the palladium and gold process of toning The method is however, uncertain in its results Its success appears to depend upon the fulfilment of certain precise conditions as yet not understood It has failed almost completely when again applied to a batch of sections with which on first trial it yielded a satisfactory result In our most successful preparations by this process granular bodies, having the exact appearance and arrangement of the granular stage of the plasmodiophora brassicæ, are present in considerable numbers in the nuclei of most of the epithelial cells and occasionally also in the protoplasm (Fig 5) They occur generally in small groups occasionally in masses There are grounds for believing that in silver gold preparations these bodies are often obscured by nucleolar matter which tends to deposit around them as they lie in groups within the nucleus of the cell Similar bodies occurring singly or in groups may be observed in some of the tissue spaces, but as various forms of degenerative granules which tend to reduce silver salts are common in this situation it is impossible to attach any special significance to them The post granular stage (B 8 and 9) is also represented but less abundantly than the preceding one The bodies corresponding in reaction and in form to this stage appear also to be present chiefly in the nuclei of the epithelial cells As they stain much less deeply than the granules they are difficult to recognise in this situation When however, an epithelial cell containing them divides by mitosis they are temporarily thrown into the protoplasm and can then very commonly be recognised (Fig 6) They may be observed in large numbers in cells in which the

that they can

that they are

less abundant (B 10 and 11) It is represented by bodies of round oval or irregular form which may be seen either in the nucleus of the epithelial cells or in the protoplasm of a dividing cell more rarely in the protoplasm of a resting cell They measure 1 3μ to 1 5μ When in the nucleus of an epithelial cell in a silver gold preparation bodies of this kind are obscured by the chromatin and nucleoli We have however been able to see them clearly in silver preparations which after toning with platinum have been stained in a special way with methyl violet (Fig 7) In these preparations the chromatin is darkened by the platinum whilst the suppo ed parasites take up the methyl violet stain We have a silver gold preparation in which these bodies lying in the protoplasm of a dividing epithelial cell of a carcinoma of the breast appear to be undergoing mitotic division More or less deeply tinted non nucleated bodies which correspond in characters *to the gametes of the plasmodiophora brassicæ* are not uncommon within the epithelial cells and in the interstitial tissues (A 12) This form is however so lacking in distinctive morphological characters that it certainly

products of tissue

are some grounds

e plasmodiophoræ associated with carcinoma are actively motile and that they may therefore at times exhibit the morphological characters of wandering cells In all silver gold preparations of carcinomata, wandering leucocytes and connective tissue corpuscles constitute a striking feature They generally stain deeply and are often thrown out into long narrow threads as they force their way between the masses of proliferated epithelial cells For a long time we assumed that all such appearances were to be regarded as merely manifestations of the phagocytic activity of these cells, although we again and again noted appearances which it was difficult to reconcile with this view These consisted especially in the occasional presence of very small deeply staining bodies stretched out into fine threads and terminating at one or both extremities in the *form of a minute knob* We have recently been able to study these bodies to better advantage in the palladium gold preparations (Fig 1, B 12 and Fig 8) They are only rarely present and a considerable search is generally required before one is found The

about 0 5μ in diameter

xtremely delicate It may

of course, no proof that these bodies are wandering gametes We simply direct attention to their presence and point out the possibility of their being of this nature Hour glass forms which would represent the conjugation of the parasites have occasionally been observed within the protoplasm of the epithelial cells and in the surrounding tissues This again is a form which is too indefinite in character to be distinguished from various products of tissue degeneration The phase of the plasmodiophora brassicæ which immediately follows conjugation has on the other hand very distinctive features We have a preparation from a carcinoma in which there is lying at the edge of proliferating epithelial cells a body in which these features are exactly reproduced upon a slightly smaller scale (*B 14*) *The next stage is that of the nucleated spores* which has already been described

It will be noted that as the granular phase is receded from the supposed parasites gradually diminish in number In this respect there is a striking difference from what obtains in kohlhernia We have, however, only to consider for a moment the comparative conditions under which the two parasites are living to find an adequate explanation The vegetable host differs from the mammalian one in having no phagocytic cells There is the most conclusive evidence *that very active phagocytosis is constantly in progress* within carcinomatous tumours This action may be manifested in tumours in which as far as can be seen, there are no dead or degenerated epithelial cells requiring to be removed As already stated the phagocytic cells may commonly be observed fixed in the act of moving about between the epithelial cells being stretched out into long winding threads terminating at either extremity in a bulb Appearances may not infrequently be noted which seem to indicate that one of these bulbs has penetrated into the protoplasm of an epithelial cell That this actually occurs seems to be borne out by *the fact that occasionally a leucocyte may* be observed to be wholly imbedded in the protoplasm of such a cell The phagocytic cells lying in the tissue spaces are commonly more or less loaded with granular débris as well as with larger particles some of which closely resemble the larger forms of the plasmodiophoræ The evidence points strongly to the conclusion that the parasites are constantly being swept up by these cells which are even capable of removing them from the protoplasm of the epithelial elements and that only those that remain within the shelter

safe from attack If this is so it is easy to

of plasmodiophoræ progressively

phase is receded from Notwithstanding that a rapid proliferation continues up to the time of the formation of the gametes the destruction of the parasites by phagocytic action is so great that only comparatively few survive to form spores A very small number of these however are capable of starting another cycle The motile myxamœbæ having penetrated into the nuclei of some of the epithelial

almost unlimited number

rapid proliferation The

that such penetration occurs in the demonstrable fact that the myxamœbæ of the plasmodiophora brassicæ are attracted to the nuclei of the vegetable cells

The cultivation of an organism resembling the plasmodiophora brassicæ from carcinomatous tumours —As already indicated we have succeeded in growing from carcinomatous tumours an organism which accurately represents certain phases in the developmental cycle of a plasmodiophora The technique which we now employ is based upon the results of many experimental attempts to obtain cultures *from such tumour* It consists essentially in placing pieces of the fresh tissue upon the dry surface of an agar medium various important details being attended to Through the courtesy of Mr F M Caird Mr David Wallace and several other surgeons we have been enabled to obtain the tumours immediately upon their removal from the patients We shall describe the procedure as carried out with a mammary carcinoma. The gland with the tumour incorporated in its substance is, immediately on its removal from the patient, received upon a thick layer of sterilised gauze swabs, an abundant supply of which is always obtainable in an operating theatre. The specimen is wrapped up in these and then further covered with a sheet of sterilised protective. It is at once removed to the laboratory at which the tissues arrive unchilled and alive. Tubes of ordinary sloped nutrient agar are in readiness. The preliminary preparation that they require consists in the removal of the water of condensation and liquefaction and re-sterilisation by heat in order that a fresh and yet somewhat dry surface, free from any condensed pellicle, may be provided for the reception of the piece of tumour. Glycerine agar has been successful in one case and we have also obtained growths upon some media of special composition which, however, did not appear to have any advantage.

A large area of the posterior surface of the specimen, which in many cases is the pectoralis major muscle, is cauterised to insure its sterility. With the aid of a pair of forceps and a scalpel, both of which have been sterilised in the flame of a Bunsen burner, the posterior surface of the tumour is exposed by dissection. Small portions are then as quickly as possible cut out with another sterilised knife and placed singly upon the surface of the agar in the prepared tubes. The tissue must on no account be allowed to fall to the bottom of the tube, as contact with even the small amount of water of condensation would almost certainly prevent a successful result being obtained. It should be placed about the middle of the agar surface. The tubes containing the pieces of tissue are transferred to the incubator with as little delay as possible. They must in the first instance be laid in a slightly inclined position, so that whilst the piece of tissue is not displaced the water of condensation does not flow over the surface. The temperature is kept at 37° C. By the second or third day the piece of tissue has become adherent to the agar. The tubes may then be placed in the erect position. To prevent undue evaporation the tubes should now be sealed by pushing the cotton-wool plug in about a quarter of an inch from the margin and filling the receptacle thus formed with melted hard paraffin obtained from the imbedding oven. In our later work with this technique we have been uniformly successful in preventing contamination of the medium. This we attribute to the favourable conditions under which we have been able to obtain the material, the extensive cauterisation of the posterior surface of the specimen, and the circumstance that we have worked in the still air of the laboratory of which we are the sole occupants. We have obtained cultures of an organism which we believe to be a plasmodiophora from four tumours—namely, one malignant adenoma of the intestine (a secondarily infected abdominal gland being used for making the cultivations) and from three mammary carcinomata. The growth does not develop at the surface but invades the subjacent medium. It appears as a faint greyish cloud in from two to seven days and generally continues to increase very slowly for about ten days more. It has as yet been found impossible to obtain a satisfactory view of the organisms in films made from these growths and stained by the ordinary methods employed in bacteriology. They are either stained in conjunction with granular matter in the medium without presenting any characteristic features or they are decolourised. It is therefore easy to understand how previous observers, when dealing with such growths, which certainly must occasionally have been obtained by some of them, have concluded that the faint cloud which formed was the result of the penetration of colouring matter or coagulable substances from the dead tissue. By hardening the medium in 5 per cent. formalin and making preparations by the silver-gold process we have been able to recognise not only that the cloudiness is essentially dependent upon the growth of an organism, but that this organism has characters which prove it to be a plasmodiophora. In the sections from the growths in agar obtained from the secondarily infected abdominal gland we have been able to demonstrate the presence of several successive phases of a plasmodiophora, corresponding exactly in form and reactions to the special method with the bodies we have described as present in sections of carcinomatous tumours. In one of the agar growths from this tumour a slight splitting of the medium had been accidentally produced by the pressure exerted in fixing the tissue on the surface. Upon the walls of the crevice so formed (which extends a considerable way into the medium) there are very numerous small bodies which have the exact characters of the myxamœbæ already described. They measure from 1·2 μ to 1·7 μ. Some are devoid of the pale centre, others present this feature, whilst others again show the black granules appearing in the centre (Fig. 9). Some of these myxamœbæ have penetrated a certain way into the subjacent agar. Masses of granules, exactly corresponding to those that develop from the myxamœbæ in the incubated kohlhernia, are also present, though only a few have been observed. Similar granules, many of them of considerably larger size, are present in abundance throughout the surrounding agar but they cannot be distinguished absolutely from the fine granular deposit which is caused by the circumstance that certain substances in the agar effect the reduction of the silver salt. The large and small post-granular phases are, however, very abundantly represented (Fig. 10). They are probably the chief cause of the faint opacity in the medium. With the aid of the silver-gold method alone we have not been able to trace them with absolute certainty into the nucleated stages, but by staining the silvered sections by a special methyl violet process this structure has been demonstrated in some of the largest forms (Fig. 11). If the presence of the immediately preceding and succeeding stages may be taken as further proof of the existence of the granular stages which intervene, then we have evidence of the presence of eight phases, or four different stages, of a plasmodiophora in this growth. In the growth from two of the mammary carcinomata we have been able to recognise only the post-granular stage but the examination of them was rendered difficult by the circumstance that the agar turned out to be of too soft a consistence for the obtaining of sections that could be manipulated with facility. The examination of the growths from the fourth carcinoma is not yet completed, although we have already satisfied ourselves of the presence of the post-granular stage of the organism. For the purpose of making control observations, we have treated in the same way portions of tissue obtained from two cases of interstitial mastitis, one intra-abdominal testicle removed for torsion of its pedicle, and one simple fibro-adenoma of the breast. In no instance has any change taken place in the medium similar to that observed in the other tubes.

The bearing of the observations made upon the question of the etiology of carcinoma.—The observations that we have made can, we believe, be shown to harmonise with, and to help to explain, many otherwise unintelligible facts already recorded in the literature of the pathology of carcinoma. Our object for the present is, however, simply to record our own observations which, depending upon the results given by a new histological process and breaking fresh ground, are capable of standing by themselves. It is obvious that if, as alleged, plasmodiophoræ are present in carcinomatous tumours many of the intracellular bodies described especially by Russell and San Felice as blastomycetes, and of those interpreted by numerous others as protozoa, are simply various phases of this species of myxomycetes, for it is hardly to be believed that more than one pathogenic organism would commonly be present. The plasmodiophora theory of carcinoma has been advocated by the workers already mentioned for many years, but the evidence that has hitherto been adduced in support of it cannot be said to be conclusive. It has certainly served to convince very few. Can the new evidence that we have obtained be regarded as serving to establish the validity of this hypothesis? In our researches we have traced what appear to be three parallel lines—namely, those of (1) the life-cycle of the plasmodiophora brassicæ, (2) a series of bodies found especially within the cells of carcinomatous tumours, and (3) the stages of an organism which can be grown from such tumours. The last line is incomplete, but through eight successive phases, or four separate stages, the parallelism is exact. With regard to the histological evidence it may be affirmed that all the stages of a plasmodiophora are accurately represented in carcinomatous tumours and that it has been found impossible to construct a similar series from control tissues. At the same time many of the bodies which correspond in form and reaction to certain of the stages of a plasmodiophora are indistinguishable from certain tissue granules. The presence of any number of tissue granules does not of course logically exclude the presence of micro-organisms which are known to have a certain resemblance to them. All that can be demanded from the histological evidence in support of a hypothesis like this is that the presence of bodies morphologically identical with the parasite as it is known in cultures or elsewhere should be demonstrated. If the supposed parasites presented no very distinctive morphological feature the evidence would certainly have very little weight. But in this case there can be demonstrated several such features of a very unusual and striking nature. The two forms of myxamœbæ, already known as they exist in the life-cycle of the plasmodiophora brassicæ, are definite forms that could not easily be simulated by the products of tissue disintegration. These forms have been observed in carcinomata and the presence of black granules in the originally clear centre of the first variety has also been noted. The bodi[illegible] plasmodiophoræ in the [illegible] been observed to be u[illegible] mitosis. The minute wandering cells which we have described cannot be identified as any cellular form known in the human subject but would exactly represent the gamete of a small plasmodiophora. Lastly, a body has been found in a carcinoma which exactly conforms to the peculiar morphological characters of that phase of the plasmodiophora brassicæ which can be shown to follow conjugation.

The evidence derived from the study of the cultures is not subject to the same ambiguity of interpretation. In the sections of the growths in agar tissue cells are absent and an organism is present which has obviously been multiplying rapidly. In one instance, at least, this organism has been found to be present in four distinct forms which harmonise exactly with four successive stages in the developmental cycle of the plasmodiophora brassicæ, as well as with that which has been found in sections of carcinomatous tissue. In cultures from three other cases of carcinoma there has also been observed an organism which is identical with the post-granular stage, as observed in the other case, and this phase is one which, in cultures at least, has a very characteristic appearance. Included in the four stages observed in the cultures from the first case are the specially-characteristic forms of the myxamœbæ and the nucleated pre-conjugation stage. This evidence seems to us to be incompatible with any other conclusion than that in these cultures we are dealing with organisms which are plasmodiophoræ. Taken in conjunction with the histological evidence of the presence of similar bodies in *carcinomatous tissues, it points to the conclusion* that plasmodiophoræ are constantly associated with carcinomatous growths of the kind from which the cultures were made.

We have not yet had an opportunity of examining cultures from a squamous epithelioma. We have, however, examined tissues from three cases by the ammonio-silver process and whilst we recognise the uncertainty attaching to histological evidence in a *question of* this kind we *can say that, as far* as such evidence justifies the expression of an opinion, this form of carcinoma is also associated with the presence of plasmodiophoræ in the cells. We have as yet no observations to record bearing upon the question of the presence of plasmodiophoræ in sarcomatous malignant growths. We strongly dissent from the recent assumption that all malignant growths must necessarily have the same origin. To discuss this question here would, however, be to go beyond the purpose of our paper. If future observations confirm those that we have here briefly recorded and it be thus establis[illegible]t in carcinomatous [illegible] the organism to these [illegible]proof, although this wo[illegible]lation experiments [illegible]ich can [illegible] is the [illegible]e con[illegible]ible to produce antibodies, by the therapeutic use of which the normal protective agencies of the body will be enabled to overcome the parasites in such growths.

In concluding, we have to express our indebtedness to the Fellows of the Royal College of Surgeons of Edinburgh and to the General Board of the Laboratory of the Scottish Asylums for the facilities they have afforded us for the carrying out of the researches recorded in this paper.

APPENDIX.

The technique of the ammonio-silver process and toning methods.—The ammonio-silver process was described in the *Review of Neurology* [illegible]

adding to a 1 per cent. solution of silver nitrate in distilled water a 5 per cent. solution of ammonia in distilled water, drop by drop, until the precipitate which forms is nearly but not entirely dissolved, and then filter. In place of this silver solution a saturated solution of silver carbonate in ½ per cent. ammonia in distilled water may be used with advantage. Two days at least should be allowed for saturation. The fluid should measure at least 50 times the volume of the tissues. Cork the bottle or specimen tube and put it in the dark. The pieces are ready for examination in from three to ten weeks.

3. Place a piece of the impregnated tissue in a bowl of water (500 cubic centimetres) to which about 2 cubic centimetres of 5 per cent. ammonia have been added. Remove the surface deposit as far as possible. This is best done simply with the aid of the fingers whilst the piece of tissue is held under water. Transfer the piece to a second bowl of ammonia and water. *Renew the fluid after about an hour and* leav[illegible]

4. [illegible] ounces or 140 gran[illegible] dissolve by boiling; [illegible]till hot; after it has [illegible]h ammonia has been added in the proportion of ten drops of a 5 per cent. solution to one ounce, immediately before use. Allow the tissue to remain in this for from 12 to 24 hours.

5. Cut thin sections on the freezing microtome. Transfer them from the knife to a bowl of water to which about ten drops of 5 per cent. ammonia have been added. After about five minutes transfer the sections to another bowl of ammonia and water, and after a similar period give them a third wash.

6. Transfer the sections to a bowl of water to which there have been added from five to ten drops of a saturated solution of citric acid in water, and allow them to remain in this for four or five minutes.

7. Place the sections in a bowl of tap water and after a few minutes transfer them to a second bowl of water. They are now ready for toning.

8. [illegible] per cent. solution of gold chloride in [illegible] 1 per cent solution of citric aci[illegible]ly into a flat bottomed white por[illegible]om the water to this toning bath by means of a glass rod or platinum needle. Allow them to *remain spread out for about one hour. About a dozen sections of* [illegible] two or three *minutes*.

10. Transfer to a bowl of tap water.

11. Dehydrate the sections with absolute alcohol, clear in equal parts of turpentine and benzole, remove turpentine with pure benzole; mount in benzole balsam.

The process of toning the sections permits of being varied in an almost endless number of ways, with corresponding variations in the [illegible] must suffice to indicate briefly the details of two special toning processes which [illegible]

Platinum toni[illegible] follows. To one [illegible] potassium chlor[illegible] solution of phos[illegible] Filter this [illegible] it for about half an hour. Wash the [illegible]n clear them in a watch-glassful of [illegible]ichloride ($PtCl_4$) in water *for about ten minutes* wash well in water, dehydrate, clear, and mount in balsam.

The conditions upon which depends the success of the combined palladium and gold toning process have not yet been definitely [illegible] The best results have been obtained with sections of a [illegible]

Edinburgh.

THE RESULTS OF TWO CASES OF INJECTION OF PARAFFIN.

By F. C. WALLIS, F.R.C.S. Eng.,
SURGEON TO CHARING CROSS HOSPITAL, ST. MARK'S HOSPITAL, AND THE GROSVENOR HOSPITAL.

CASE 1.—A single woman, aged 32 years, was sent to me by Sir Francis Laking on Nov. 2nd, 1904, because of considerable and *increasing difficulty in getting the bowels to* act. The history given was that the present condition had been gradually arrived at and the patient was getting thinner. The difficulty of procuring any action of the bowels was now considerable and was accompanied by slight loss of blood. There were a dull aching pain and feeling of weight in the rectum and some slight difficulty in passing urine. On examination the rectum was not in itself found to be the cause of the trouble but a large tense swelling in Douglas's pouch was felt which was evidently causing the obstruction. Examination of the abdomen revealed a swelling in the right side of the hypogastrium. Above the pubes and to the left there were some hard, rounded lumps to be felt. Dr. R. A. Gibbons saw the patient the same day and elicited the information that because of prolapse of the uterus paraffin wax had been injected into the broad ligaments two years previously. The patient's temperature was normal and up to the time she consulted me she had been carrying out the details of her ordinary daily life.

On examination per vaginam (under an anæsthetic) the vagina was found to be considerably invaded by the swelling felt per rectum, the cervix was high up, and around it various hard round lumps could be felt. The uterus was not fixed. The tumour was obviously one of three things: an ovarian cyst, a parovarian cyst, or some collection of fluid in the broad ligament the result of the paraffin injection. Whichever it was, the necessity for operation was somewhat urgent.

On Nov. 9th I opened the abdomen, Dr. C. H. Roberts assisting me. I found a large tense swelling filling up the pelvis but there was no indication of a cyst in connexion with the uterine appendages and the swelling was adherent everywhere. In such circumstances it was not considered advisable to attempt anything further by the abdomen and the incision was closed by two continuous silk sutures for the peritoneum and fasciæ and interrupted fishing-gut sutures for the skin. With the patient in the lithotomy position the swelling was incised through the posterior wall of the vagina. Nearly 40 ounces of inodorous pus were evacuated mixed with a considerable amount of paraffin which came away in lumps and flakes. The incision was enlarged sufficiently to allow a digital examination of the abscess cavity. Various masses of paraffin could be felt but they were firmly fixed and the wall between them and the peritoneal cavity was so thin that no attempt was made to remove them. The cavity was washed out and a large-sized drainage-tube was introduced and sutured to the vaginal opening. The abscess cavity was irrigated twice daily with sterilised water, after which some peroxide of hydrogen was introduced. The cavity disappeared rapidly and at the end of 12 days a probe could only be passed one and a half inches through the incision in the vaginal wall and this small sinus soon healed. The abdominal incision healed well and the skin sutures were removed on the eighth day.

Everything went well until the twentieth day when there were a rise of temperature and some abdominal tenderness and swelling on the right side; this increased for the next three days. No definite swelling was felt per vaginam and I determined to reopen the abdominal wound, as it seemed possible that there was suppuration under the right rectus muscle. Under the anæsthetic the abdominal walls, which previously were rigid and extremely tender, became relaxed and moved freely. A small incision was made at the side of the former incision. The tissues were found to be quite healthy. The abdomen was opened and a large tense swelling was seen lying immediately under the right rectus. This was considered to be another separate collection of pus situated anteriorly and the abdominal incision was closed. Both Sir Francis Laking and Dr. Gibbons thought it highly desirable to wait until the swelling could definitely be felt in the vagina. This I decided to do.

The day after the second operation the temperature fell to normal and remained so. The abdominal swelling and tenderness rapidly diminished and at the end of a week, when the stitches were removed, the swelling had almost disappeared and there was hardly any tenderness. The patient left the nursing home to go to the seaside six weeks after the first operation, feeling and looking well, but there was still some tenderness under the right rectus on firm pressure.

CASE 2.—A woman, aged 66 years, was admitted into St. Mark's Hospital under my care on April 11th, 1904. She gave the following history. For three or four years previously she had suffered from prolapse of the rectum, the bowel protruding about three inches. Late in January, 1904, she was admitted into a hospital where she underwent operation, apparently by the injection of paraffin wax into both ischio-rectal fossæ; she was in hospital six weeks altogether. A fortnight after leaving the hospital she "felt something burst behind" and noticed that her linen was covered with a white, waxy substance; since that time she had had a constant discharge from a small sinus in the right peri-anal region. The bowel had not prolapsed so much since the operation but she had suffered a good deal of pain in the back which was worse when sitting down.

On examination there was a hard, tender lump in the left buttock close to the anus; the skin over the lump was hot, dusky-red, and tender. On the right side, about half an inch from the anus, was the orifice of a sinus which ran up by the side of the rectum for about two and a half inches. A probe passed into the sinus could be felt beneath the mucous membrane but no definite internal opening could be made out. On squeezing the sinus small portions of wax and a little thin pus could be expelled. The patient was advised to return to the hospital at which she originally attended for further treatment, as this course on the whole seemed to be the most satisfactory. I have to thank my house surgeon, Mr. F. A. Johns, for the notes in this case.

Whether the injection of paraffin into the broad ligament is ever advisable or even justifiable is a question upon which I should like a definite opinion from those who make a special study of the uterus and its appendages. The ultimate results in Case 1 were disastrous enough and there is no assurance that a recrudescence of the trouble may not occur at any time. Supposing that the paraffin is sterile at the time of injection, which is doubtful unless special precautions are taken, this is no guarantee that it will always remain so and, as these cases illustrate, it may possibly act as a culture medium in a part of the body where pyogenic micro-organisms always abound. The result in Case 2 is also unsatisfactory and having regard to the excellent results obtained by other methods in cases of prolapsus ani I do not think that the injection of paraffin wax is to be advocated.

The injection of paraffin wax has been used for cases of incontinence after excision of the rectum, but the result is not a success, there cannot be any *control* obtained by this injection. The paraffin wax forms a number of lumps round the lumen of the bowel, which is partially occluded, but the contents of the bowel escape as readily as before between the lumps. These remarks are not meant in any way to detract from the merits of this treatment in certain cases. The good results obtained are well known. The injection of paraffin wax, however, like many other new treatments, has been taken up and used without discrimination and unless this is checked a treatment which in proper cases produces excellent results may fall into disrepute.

Harley-street, W.

ON THE RELATION BETWEEN VARIOUS ATMOSPHERIC CONDITIONS AND THE OCCURRENCE OF CEREBRAL HÆMORRHAGE.

By JAMES W. RUSSELL, M.A., M.D. CANTAB.,
M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE BIRMINGHAM GENERAL HOSPITAL.

DR. R. Hensleigh Walter has suggested[1] that in certain cases a high barometric pressure is a factor in deciding the onset of an attack of cerebral hæmorrhage, the especially favourable condition being, in his opinion, a sudden rise in the barometer following a more or less continued period of depression. Dr. Walter's letter was followed by others in support of his suggestion, in one of which the writer stated that he fully expects to be called to a case of cerebral hæmorrhage when the barometer has risen high and become anti-cyclonic. Other writers were in favour of a rise or fall in temperature as a probable exciting cause, especially when associated with changes in the atmospheric pressure, and it was evident that a belief in a causal relationship between atmospheric changes and the onset of apoplexy exists in the minds of many practitioners. The question can easily be put to the test and having recently collected for other purposes the cases of cerebral hæmorrhage admitted into the Birmingham General Hospital from the summer of 1885 to the end of 1902 I have the material ready to hand My information as to the atmospheric *conditions existing on the days of onset has been obtained* from the records of the Edgbaston Observatory kept by Mr Alfred Cresswell, but as these have only been published since the beginning of 1891 only the cases occurring since that date have been available

---

[1] Brit. Med. Jour., April 9th, 1904.

I have records of 66 fatal cases of cerebral hæmorrhage admitted into the General Hosp [illegible] all of which the diagnosis was [illegible] examination There are furthe [illegible] fatally (excluding those in which the exact date of onset was not determinable) which appear to me to have been *probably due to hæmorrhage In these however, the* diagnosis is somewhat open to question and it is possible that a certain number of cases of thrombosis may have been included and that others due to hæmorrhage may have been omitted The inferences from these cases must therefore be regarded as to some slight extent doubtful and the two series have been throughout kept apart

Barometric pressure —The barometric readings from which my figures are obtained were taken at 9 A M They therefore only approximately represent the pressures obtaining at the actual moment of onset But this source of error is hardly avoidable, especially as the notes often give no clue as to the time of day at which the attack began The standard of comparison adopted is the average pressure for the 12 years involved This I have ascertained, amounts to 29 376 inches The pressures recorded on the days of onset are as follows —

	Fatal	*Non fatal*	*Total*
Above the average	37	34	71
Below the average	29	28	57

A larger number of cases therefore occurred on days on which the barometric pressure was above the average than on those when a pressure below the average was recorded the proportion in the total number of cases being almost exactly as 5 to 4 The relationship to the higher pressures of each month is shown in the next table —

	Fatal	Non fatal	Total
Occurring on the day of the maximum pressure of the month	3	3	6
Occurring on days with the pressure differing from the maximum pressure of the month by not more than 0 1 inch	8	5	13
Occurring on the day after the maximum pressure of the month	4	3	7
	15	11	26

These figures are probably to some extent matters of coincidence but they are considerably in excess of similar figures obtained with regard to the minumum pressure of the month thus —

	Fatal	Non fatal	Total
Occurring on the day of the minimum pressure of the month	1	3	4
Occurring on days with the pressure differing from the minimum pressure of the month by not more than 0 1 inch	4	2	6
Occurring on the day after the minimum pressure of the month	3	2	5
	8	7	15

Some little connexion between the onset of apoplexy and the higher pressures of the month seems thus to be suggested But it is possible that variations in pressure may be of greater importance than the absolute height of the barometer In order to work this out I have investigated the pressures recorded on the three consecutive days on the middle one of which the attack occurred The explanation of the signs used is as follows —

<> = a day of higher occurring between two days of lower pressure

< = three successive days of rising pressure

> = three successive days of falling pressure

>< = a day of lower occurring between two days of higher pressure.

The following are the results —

	<>	<	>	><
Fatal	11	23	16	16
Non fatal	18	19	12	13
	29	42	28	29

A considerable excess of cases therefore occurred in the course of a steadily rising barometer In 19 of these the total rise exceeded 0 4 inch, in nine it exceeded 0 5 inch but *in only* one was it more than one inch

Taking the day of onset alone, 71 cases occurred with a rising barometer compared with 57 noted when the barometer was falling The proportion is again almost exactly as 5 to 4 and the evidence in favour of absolute height and of rise from a lower to a higher level as a factor in the causation of hæmorrhage is identical The inference would probably be in favour of absolute height as the important factor

Temperature —It has been stated that cerebral hæmorrhage occurs more frequently in the colder months of the *year This was the case in the 241 cases admitted into the* General Hospital since the summer of 1885 134 occurring from November to April inclusive, against 107 from May to October

	Fatal	Non fatal	Total		Fatal	Non fatal	Total
January	11	12	23	July	9	10	19
February	13	12	25	August	9	16	25
March	7	16	23	September	5	12	17
April	8	13	21	October	8	5	13
May	*7*	*9*	*17*	*November*	*6*	*15*	*21*
June	*7*	*10*	*17*	*December*	*9*	*12*	*21*

But the part if any, played by temperature is more likely to be demonstrated by examining the daily fluctuations This I have attempted to do by comparing the maximum and minimum temperatures recorded on the day of onset with the respective averages for the month

	Fatal	Non fatal	Total.
Maximum temperature above the average	32	33	65
Minimum ,	32	29	61
Maximum below	34	29	63
Minimum	34	33	67

Temperature in itself is therefore not shown to have any effect in deciding the onset of an attack Not much more can be said for the combined effects of barometric pressure and temperature as shown below —

	Fatal	Non fatal	Total
B + and T +	20	19	39
B + and T −	17	15	32
B − and T +	13	14	27
B − and T −	16	14	30

Where B = barometric pressure T = maximum temperature and *the signs + and − represent excess over the average and the reverse*

Changes in temperature have been examined by taking the records on three consecutive days as before —

	<>	<	>	><
Fatal	11	19	12	24
Non fatal	14	17	17	14
	25	36	29	38

The only possible suggestion that can be drawn from this table is that a rise of temperature on any particular day is slightly *favourable to the occurrence of an attack 74 or* 57 8 per cent of the cases occurring on days on which a rise of temperature was in progress But this excess is only shown in the fatal cases

The effect of combined changes in pressure and temperature on the actual day of onset is shown in the next table in which the fatal and non fatal cases are taken together —

[illegible]	41 cases.
	24 ,
	30
Barometer falling and temperature rising	32

In one case the same temperature was recorded on two successive mornings The suggestion is that a combined rise of pressure and temperature is favourable to the *occurrence of cerebral* hæmorrhage , but in only 11 of the 41 cases of combined rise was the difference between the maximum temperature on the day of onset and that of the following day greater than 5° and with only three exceptions this rise corresponded with a rise of barometric pressure of less than 0 2 inch The evidence in favour of combined rise of pressure and temperature as a causal factor is thus extremely small and on the whole it seems *fair to conclude that temperature apart from season,* exerts little influence in the determination *of an attack of* apoplexy

Wind pressure.—The extreme pressure of the wind for each day is only recorded at the Edgbaston Observatory when it amounts to not less than 0·5 pound per square foot and in order to obtain the average pressure I have estimated it at 0·25 pound on those days on which no record is entered. The average extreme pressure for the 12 years is then 2·2 pounds. The cases are distributed as follows:—

	Fatal.	Non-fatal.	Total.
Above the average	24	12	36
Below the average	42	50	92

Here the figures for the first time give a very definite result. the cases occurring on days of low wind pressure being 2·6 times as numerous as those which occurred when the wind pressure was above the average. This result must be taken for what it is worth. It is hard to believe that variations in wind pressure can play any part in the causation of apoplexy and a larger number of cases might, of course, dispose of the inference, but if statistics are worth anything in such matters the preponderance of cases on days of low wind pressure is almost too marked to be the result of coincidence only.

The final table shows the distribution as regards wind pressure and barometric pressure combined:—

	Fatal.	Non-fatal.	Total.
B. + and W. + ...	7	5	12
B. + and W. –	30	29	59
B. – and W. + ...	17	7	24
B. – and W. –	12	21	33

There is thus a very marked preponderance of cases on those days on which a high atmospheric pressure was combined with a low wind pressure.

Conclusions.—There seems to be a slight tendency towards the occurrence of cerebral hæmorrhage on days of high atmospheric pressure and also on days of rising pressure, the former being probably the important factor. There is a very marked tendency on days of low wind pressure and the combination of a low wind pressure with a high barometric pressure is the condition under which the largest number of cases took place. Apart from season, temperature in itself has not been shown to exert any influence, though a small excess of cases has been noted on days with a rising thermometer and also with a combined rise of atmospheric pressure and temperature.

Birmingham.

THE OVARIAN LIGAMENT AND ITS RELATION TO PREGNANCY OCCURRING AFTER ABLATION OF THE OVARIES.

BY JOHN H. DAUBER, M.B., B.CH. OXON., M.R.C.P. LOND.,
PHYSICIAN, WITH CARE OF OUT-PATIENTS, TO THE HOSPITAL FOR WOMEN, SOHO.

MORPHOLOGY often throws light upon phenomena which are otherwise obscure and not easy of comprehension. Several cases have been placed on record where pregnancy has taken place notwithstanding the complete removal of both ovaries. Such cases naturally excite considerable interest. They are generally explained by the assumption that both ovaries have not in truth been entirely removed. Every operator knows how difficult, nay, impossible, it is in many instances of cystic and inflammatory conditions of the appendages to assert with absolute confidence that every trace of ovarian tissue has been taken away. Some of the cases recorded, however, seem indubitably to disprove this source of fallacy and it is generally believed either that accessory ovaries or additional patches of ovarian tissue like accessory thyroids in the neck may exist in the broad ligaments or that traces of ovarian tissue are present in the ligament of the ovary and are responsible for the ova which become fecundated under these unusual conditions. It is to be remembered that a single Graafian follicle is enough to accomplish the purpose. A consideration of the morphology of the ovarian ligament makes the presence of Graafian follicles within it easily understandable and as the commonest facts are apt to be forgotten a reference to the subject may perhaps be excusable.

Hertwig, in his "Lehrbuch der Entwicklungsgeschichte," says of the inguinal ligament:—

> The band is divided into three parts—the first from the lower end of the ovary to the uterus; the second part from the uterus to the inguinal region, the ligamentum teres; the third the uppermost, connecting the parovarium with the hilum of the ovary.

McMurrich ("Development of the Human Body") speaks of its origin thus:—

> From each genital ridge a prolongation of mesenchyme extends downward in the mesentery of the ridge, nearly parallel with the Mullerian duct, with which it comes into contact at the part where the two ducts fuse and thence is continued downwards and forward between the folds of the broad ligament to be attached to the ventral wall of the abdomen in the inguinal region. The upper part of this prolongation of the genital ridge represents the ligament of the ovary and its lower part the ligamentum teres of the female, while in the male the entire structure forms what is known as the gubernaculum testis.

Further—

> The change of position [of ovaries and testes] is partly due to the rate of growth of the inguinal ligaments being less than that of the abdominal walls, the reproductive organs being thereby drawn downward towards the inguinal regions where the ligaments are attached. The attachment is to the bottom of a sli [illegible] hich projects a short distance into the substa [illegible] and is known as the canal of Nuck in the [illegible] the vaginal process. In the female a second [illegible] mentioned. The relative shortening of [illegible] alone would draw the ovaries toward [illegible] fusion of the lower ends of the Mullerian [illegible] ments are united with these, produces a [illegible] line so that the organs come to lie finally in the true pelvis.

Heisler ("Text-book of Embryology") says:—

> The inguinal ligament in the female extends from the primitive position of the ovaries in the lumbar region of the abdominal cavity to the groin where it passes through the abdominal wall, traversing the inguinal canal, to terminate in the labium majus. The upper part of the ligament *containing involuntary muscular substance* firmly unites with the ovary. In the third month the ovary descends to the lower part of the abdominal cavity and is now connected by the succeeding portion of the inguinal ligament with the uterus. This connexion may be a factor in the final position of the ovary—that is, its descent into the true pelvis. The part of the inguinal ligament that passes from the ovary to the uterus is the permanent ligament of the ovary, while the remaining portion, which passes from the uterus through the inguinal canal to the labium majus of the vulva, is the round ligament of the uterus. [illegible] perforates the abdominal wall a small [illegible] goes with it. Normally, this peritoneal [illegible] bliterated.

Arthur Keith ("Human Embryology and Morphology") describes these ligaments in the following terms:—

> The round ligament of the uterus is attached to the Mullerian duct on each side. The point of attachment marks the *junction of the* uterine and Fallopian segments of the Mullerian ducts. The round ligament corresponds to the gubernaculum testis in the male and its development is similar. ...... Part of the Wolffian ridge is continued backwards as a peritoneal fold to the groin, this part forming the inguinal fold. Into this peritoneal fold muscle cells grow from the rudiments of the *transversalis* and internal oblique in the abdominal wall and form the round ligament of the uterus. The point from which the ingrowth springs becomes the internal abdominal ring. Others grow out into the labium majus carrying with them a process of peritoneum, the canal of Nuck. The inguinal canal and external abdomi [illegible] art of [illegible] us formed [illegible] uro- [illegible] the diapl [illegible] laris. [illegible] mes the [illegible] ld of peritoneum, the inguinal fold or plica gubernatrix, continues the *common uro-genital mesentery to* the groin. The gubernaculum testis is developed in the plica gubernatrix; in the corresponding fold in the female the round ligament of the uterus appears.
>
> There is no trace of the inguinal canal in the third month; the various layers of the abdominal wall are unbroken. In the fourth month the deep muscular layer of the abdominal wall composed of the internal oblique and transversalis bends inwards and expands the plica gubernatrix with muscular and fibrous tissue. The tissue (in the male) does not stop short at the uro-genital ridge and Mullerian *duct as in the female* but grows up and seizes the *caudal pole of* the testis.

Heisler states, with Bland-Sutton, Strangeways, and others, that involuntary muscular tissue extends to the ovary. Schäfer writes of it as follows:—

> *The reproductive* gland is in both sexes at first attached *directly* to the Wolffian body which itself is attached by a fold of peritoneum to the back of the abdominal cavity, the mesorchium or mesovarium. A band also passes from the Wolffian body upwards to the diaphragm and another containing involuntary muscular fibre—the plica gubernatrix—runs down towards the groin from the lower part of the Wolffian body and the duct.

From the foregoing extracts it will be seen that up to the present great uncertainty exists as to the exact mode of origin of the inguinal ligament and especially of the muscular tissue it contains. Is it laid down *in situ?* Does it grow downwards or upwards or both? Are testicle and ovary dragged down by the muscular fibres of the inguinal ligament or are they to some extent at least retained in place by the ligament while the fœtus grows, or is the process a mixed one? If the ligament of the ovary containing muscular fibres seizes the caudal extremity of the ovary and *exerts traction upon it it is easy to understand how* ovarian tissue may be dragged into its proper substance and be left behind after removal of the ovary and ligation of the ovarian ligament. As the fœtus grows traction may be made both ways upon the ovary as the uro-genital mesentery becomes stretched out. The upper portion of the uro-genital mesentery, the ovario-pelvic ligament, may be con- [illegible] its original attachment to [illegible] nd as the diaphragm recedes [illegible] appear that some traction is made upon it in fœtal life so that it would not be surprising to find Graafian follicles in the ovario-pelvic ligament as well as the ovarian ligament. I have myself seen on two occasions great elongation of the ovaries—in one instance amounting to three and three-quarter inches by measurement immediately after removal, without manipulation—not that the hypertrophy in these cases could be attributed to traction of the ovarian ligaments. To me, however, it is quite conceivable that traction may in some instances account for the presence of Graafian follicles within the ovarian ligaments.

The consideration of ovarian hernia throws little light *upon the problem because the inguinal ligament is attached* to the cornu of the uterus in such cases as in normal conditions, except that it may drag upon the uterine cornu. If the ovary were dragged into the inguinal canal by a true [illegible] us but [illegible] stis, it [illegible] to be [illegible] ccompanies the ovary into the sac—often together with an *enterocele, as Langton has shown. It appears to be a true* hernia or protrusion of the viscus into a patent or potentially patent diverticulum of peritoneum, as in femoral and obturator herniæ. The whole subject of the relation of the ovary and ovarian tissue to the ligaments does not appear to have been worked out very fully. Works on veterinary anatomy and comparative anatomy hardly allude to it. I cannot but think that the matter is worthy of more attention than it has hitherto received.

Charles-street, W.

A CASE OF SEPTATE UTERUS AND VAGINA; *PREGNANCY IN THE RIGHT HALF*; DELIVERY.

BY CLAYTON A. LANE, M.D. LOND.,

CAPTAIN, I.M.S.

A BENGALI female, aged 25 years, was admitted into the Eden Hospital, Calcutta, on March 13th, 1901, for her con*finement, she being in pain at the time.* She stated that she began to menstruate at the age of 12 years, the flow since then having been regular, free, painless, and lasting for seven days. She had last menstruated in August, 1900. On examination the abdomen showed a swelling limited almost entirely to the right half; it reached to the rib margin above and disappeared into the pelvis below; its left margin, running from above downwards and to the left, crossed the middle line at the level of the umbilicus. The swelling was tense and the outlines of the child could only indistinctly be made out. On examining by the vagina there was a thick fleshy septum dividing the vagina into two lateral halves, each of which was as capacious as the other. With a finger in each half of the vagina two distinct external ora could be felt. The two halves of the cervix were firmly united and not moveable upon one another, nor could any anterior or posterior groove be made out in the cylindrical cervical mass. Vaginal examination gave no clue as to which half of the uterus contained the fœtus, but from the lateral deflection of the fundus to the right there remained little doubt that the child lay in that half, and that the left half formed part at least of the mass which lay to the left of the mid-line at the pelvic inlet. She had no discharge of blood and her pains disappeared, so she left hospital five days later. She was readmitted in labour on May 20th, 1901. It may be here stated as illustrating the value of histories given by natives of India that she now said that her menstruation lasted as a rule only two days. She had been in labour for five hours *and on examination of the abdomen the uterine tumour still* lay obliquely, the fundus being entirely to the right of the mid-line, and the left border crossing this two inches above the umbilicus. The lower segment, on the other hand, lay more to the left than to the right of the mid-line. On vaginal examination the septum between the two halves of the vagina was still intact for the lower inch, but above this it was torn through, so that when one finger was introduced into each half of this passage they met beyond the remaining bar. Above this bridge of tissue was felt the intact bag of membranes inclosing the presenting part, which consisted of the breech and both feet lying in the first position. With each pain the child was forced down against, and directly impinged upon, the remains of the vaginal septum, so that this bridge of tissue formed a definite barrier restricting the further progress of the child. It was accordingly cut through and each half clamped to stop some oozing which was taking place from the cut surfaces. The perineum was somewhat rigid and the vulval orifice was narrow. The pains being good, the membranes were ruptured and the case thereafter left to nature until the breech was widely distending the perineum. The forceps clamping the remains of the septum were then removed and the child's legs were brought down without traction being made on the body. Progress then ceased, the pains lessened markedly in frequency, and the legs became blue. The hand was accordingly introduced into the vagina and both arms were brought down; they were not extended and were released without difficulty, but the necessarily rapid introduction of the hand past the breech, which was already distending the perineum, caused rupture of the latter as far as *the anterior edge* of the sphincter ani. By extending the legs of the child over the mother's pubes the face was born and the child was enabled to breathe, although the vertex was retained in the passage for another minute. The [illegible] The placenta was expressed on [illegible] The cut edges of the septum [illegible] atgut sutures, one suture lying on the anterior and one on the posterior wall of the now single vagina. Examination showed the remains of the torn *upper part of the vaginal septum.* The rent had extended up to the cervical portion of the septum, reaching as far as the internal ora, so that there was now a single cervical, just as there was a single vaginal, cavity. When the finger was passed into the cervical cavity it impinged at the level of the junction of the body and cervix of the uterus upon the lower edge of that part of the septum which divided the body into two lateral halves. Into the left half it was just possible to pass the finger to its whole extent, the sur*rounding walls being in contact with it on all sides, while* into the right half the finger entered easily and revealed a capacious cavity. The perineum was then sutured, a continuous catgut suture being used for the mucous membrane and four interrupted silkworm-gut sutures for the more superficial parts. Some oozing from the uterine cavity was checked by the intramuscular injection of 10 minims of ergotin. The patient's subsequent progress was satisfactory. Her temperature rose to 100·6° F. the same evening but fell to 98·4° at midnight; the highest points touched subsequently were, on the second day 99·4°, on the third 99·2°, and on the fourth 100·4°, after which it did not again rise above normal. The discharge followed the usual course and ceased on the eleventh day. On the thirteenth day the perineum had quite healed and was of good depth. The torn septum had nearly disappeared, being only represented by a markedly visible median raphe, palpable as a firm cord, and continued on to the anterior and posterior surfaces of the vaginal cervix as a median red line. Except for this the cervix did not appear unusual. There was a single external os, patulous, about three-quarters of an inch wide, admitting the tip of the finger, which could then just feel the persistent remains of *the septum between the two halves of the cavity of the* uterine body. On bimanual examination the body of the uterus was anteflexed. It appeared to be single, no groove being palpable on either surface or on the fundus. It was wider than normal from side to side but not from before backwards, and it was symmetrical, the two halves appearing to be of the same size. The pelvic cavity, as estimated by the finger in the vagina, did not appear to be wider from side to side than usual. The length of the intercristal diameter was 9·875 inches and that of the interspinous 7·5 inches.

Judging by the number of cases reported a septate uterus and vagina with pregnancy in one-half appears to be a far less common abnormality than is bifid or bicornute uterus, with or without a septate vagina associated with the same condition. So far as could be ascertained with the references at my disposal here there had only been two similar cases described in English literature up to the end of the year 1901, the date at which this note was originally written. One case was published in 1888.[1] The woman was pregnant twice. In the first labour she was seen by Dr. Culpin and Dr. G. E. Herman. At this time the upper part of the vaginal septum was torn, the lower part remaining intact. In the second labour the remains of the vaginal septum were torn but it does not appear that the intercervical septum tore, for it is expressly stated that during labour the head could be pushed aside and the os (presumably the external os) of the unimpregnated side felt. On this occasion she was examined by Mr. W. H. Plaister and Dr. Herman. The second case is one described by Dr. Wallace.[2] The left half of the uterus was the seat of pregnancy; it was hard to the feel, and the right half is described as feeling like a "muscular mass on a muscular cyst." The description of the labour was promised when it occurred but it does not seem to have been published. Recently two more cases have been described. Dr. Pery[3] has reported in the *Revue Mensuelle de Gynécologie, Obstétrique, et Pédiatrique de Bordeaux* a case of a labour at six months in which the right half of a septate uterus contained the fœtus. The condition of the uterus and its relations to the abdominal wall were almost exactly as described in the case now reported when she first came under observation with false labour pains. During labour the lower third of the septum which was present between the two halves of the vagina was torn. There had been no menstrual hæmorrhage from the left half of the uterus during pregnancy, but a decidua seems to have been passed before Dr. Pery was summoned and was thrown away by the midwife. He is of opinion that pregnancy had also occurred in the left half. Lastly, in THE LANCET[4] there is a full report by Dr. J. H. E. Brock of a case which he considers to be one of uterus didelphys because the two halves were moveable on one another and crossed one another diagonally. The patient went through one pregnancy and labour without anything occurring to suggest that there was any abnormality of the parts. She then consulted Dr. Brock for dyspareunia and on examination the septum dividing the vagina into two halves was discovered and removed. Two years later she became pregnant in the left half of the uterus, the abdominal condition at term being almost exactly that described in the case now published except for transposition, while vaginally the two halves of the cervix lay diagonally and the bodies were felt to cross one another. The labour passed off uneventfully.

In the case now reported no rectal examination was made with a view to determine whether the two halves of the uterus could be moved one on the other. This was not perceptible per vaginam, nor were the two halves of the uterus diagonally placed before, during, or after labour; and in addition it is to be noted that the thickness of the intra-uterine portion of the septum, as indicated by the portion left untorn after labour, did not appear to be such as to suggest that it was made up of the loosely attached halves of a double uterus. All the facts appear to point to the conclusion that the case was one of septate uterus and vagina and not uterus didelphys. In conclusion, I am much indebted to Lieutenant-Colonel F. S. Peck, I.M.S., for his kind permission to publish this case.

RUSSIAN MEDICAL STUDENTS. — The *Novoe Vremya* says that in view of the war, the liberation of medical students at the Military Medical Academy will be advanced this year as it was last. The final examinations will begin in the first half of March and will close in the middle of May. In any case the number will be very small as they can be selected from only 70 students.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF DEPRESSION OF THE LEFT PARIETAL BONE IN AN INFANT WITH MARKED PRESSURE SYMPTOMS.

BY D. ASHLEY WILSON, M.B., CH.B. GLASG.,
HOUSE SURGEON (OUT-DOOR DEPARTMENT) TO GLASGOW MATERNITY HOSPITAL.

THE patient in the present case was a boy who was born at full term on Dec. 10th, 1904, the mother being a primipara and married. She was well developed and the pelvis showed no abnormality, the following being the measurements: intercristal diameter, ten inches; interspinous diameter, nine and a quarter inches; external conjugate diameter, seven and a half inches; and diagonal conjugate diameter, four and a half inches. After a labour in which the first and second stages lasted 13 hours the child was born somewhat precipitately, resulting in an incomplete tear of the perineum. The child, on inspection, was found to have a marked depression of the left parietal bone, somewhat oval in shape, measuring three inches in length and two and a quarter inches across. It occupied the upper two-thirds of the bone. On Dec. 11th, 30 hours after birth, the child developed marked symptoms of cerebral irritation. The arms became flexed and rigid and there were constant twitchings of both hands and fingers but more especially on the right side. The feet showed twitching movements to a less extent. The head was drawn to the right side and there were present also twitchings of the eyes and mouth but no definite squint or abnormality of the pupillary conditions.

As the pressure symptoms showed no signs of improvement the following operation was performed on the evening of Dec. 12th, 24 hours after the commencement of the symptoms. A flap was reflected and the bone having been incised just below the lower border of the depression a periosteal elevator was introduced between the bone and the dura mater and the depression was raised gradually. The wound was then closed and a dressing was applied in the ordinary way. The symptoms gradually diminished until 35 hours after operation, when the child slept well, and since that time there has been no reappearance of the twitchings. The patient has made an uninterrupted recovery and on Dec. 22nd, when the dressing was removed, the wound was found to have healed by first intention.

I have to thank Dr. J. M. Munro Kerr, under whose care the mother and child were, for the facilities which he has afforded me and also to thank Dr. N. C. Rogers for permission to make extracts from the ward journal.

Glasgow.

A CASE OF SEVERE COUGH AND LOSS OF WEIGHT DUE TO ROUND WORMS IN THE INTESTINE.

BY PROSPER ST. LEGER LISTON, L.R.C.P., L.R.C.S. IREL.

THE following case is, I think, of sufficient interest to be recorded.

The patient was a boy, 13 years of age, who measured 4 feet 11 inches in height and weighed 36 pounds. He was brought to me months ago suffering from an intense earache. His mother told me he had been taken to several medical men who told him that he was "in consumption." He had had cough, expectoration, and night sweats, the expectoration being often blood-stained, and was wasted to an extraordinary degree. His temperature was 104° F. His abdomen was enormously distended and painful, there was great diarrhœa, he had no appetite, and very rarely had more than one hour's rest at night. The family history showed that two sisters had died from some vague stomach trouble. "On examining his throat I found an intestinal worm with its head firmly wedged into the Eustachian opening and I had great difficulty in pulling it away, after which the boy experienced immediate relief.

I prescribed santonin, calomel, and scammony for a fortnight and at the end of that time he voided, either by vomiting or per rectum, 603 round worms, varying in length from four to nine inches. Since this clearance his cough has disappeared, he has gained 14 pounds in weight, and his appetite has returned.

WESTMINSTER HOSPITAL.

A CASE OF CONJUNCTIVAL ARTHRITIS IN AN ADULT.

(Under the care of Dr. W. MURRELL.)

A MAN, aged 25 years, was taken to Westminster Hospital in an ambulance on Sept. 21st, 1904, suffering from what was supposed to be rheumatic fever. The history was that on the previous day, being then in perfect health, he had an attack of acute double conjunctivitis followed in a few hours by inflammation of the right wrist and the left knee. The patient on admission had a temperature of 101·8° F. and was sweating profusely. On examination it was found that the wrist itself was not involved but that there was considerable effusion into the cellular tissue of the dorsum of the hand, which was dome-shaped and boggy, [illegible] mistaken for chirag[illegible] tender but contai[illegible] inflammation in the [illegible] and the left elbow and the right knee were attacked. The temporo-maxillary, sacro-iliac, and sterno-clavicular articulations were not implicated. The patient was placed on full doses of salicylate of sodium, first of the synthetic and then of the natural salt, but without amelioration of the symptoms, the temperature ranging from 100° to 102° daily for many weeks. There was no cardiac complication and no pericardial rub or effusion could be detected. There was no tonsillitis and there was no history of syphilis, gout, or alcoholism. A gonorrhœal history was suspected but the patient denied any attack past or present and squeezing the urethra gave a negative result. The urine was of specific gravity 1020, acid, and contained no albumin. No flocculi were at any time observed in it. There was a history at the age of 22 years of an attack of acute rheumatism of some weeks' duration. The œdema of the hand continuing the fingers were carefully examined but no abrasion or wound could be detected and the temperature was not of a hectic type. The eyes were treated with boric acid lotion and a simple ointment but without improvement in their condition, and on Oct. 7th, in addition to the conjunctivitis, there was much ciliary congestion. The patient having derived no benefit from the salicylates was given first aspirin and then iodide of potassium in full doses, but again without benefit. On the 10th, there being effusion into the right knee-joint, it was aspirated and the fluid submitted to Dr. R. G. Hebb, who reported that no micro-organisms were found in the films and that there was no growth in any of the media after four days. On the 18th there was a renewed attack of acute purulent conjunctivitis of the left eye, for which Mr. G. Hartridge prescribed a 5 per cent. solution of argyrol, the application of which promptly relieved the inflammation. The conjunctival secretion was examined by Dr. Hebb but no gonococci were found. The patient had several subsequent attacks both of conjunctivitis and arthritis of gradually decreasing severity and he was discharged on Nov. 15th, relieved of all his symptoms.

Remarks by Dr. MURRELL.—This case of multiple arthritis presented many points of interest and much difficulty was experien[illegible] In favour of its being [illegible] of a previous attack, [illegible] hough on that point there was no positive evidence. Against this theory was the absence of an initial tonsillitis, the rebelliousness to the salicylates, the cellulitis of the dorsum of the hand, and the freedom from cardiac complications. The diagnosis of gout was not seriously entertained and, apart from other considerations, the duration of the attack negatives that view. From the first a suspicion was entertained that it was a gonococcic infection and the effusion into the tendon sheaths *strongly supports that view.* The absence of a urethral discharge cannot be held to overweigh the general evidence in favour of that theory. The fact of gonococci not being detected in the fluid from the knee-joint cannot be regarded as conclusive and it is probable that the conjunctival secretion was examined too late in the progress of the case to carry much weight. It will be remembered that gonococci in the ophthalmic secretion were discovered by Darier in 1889 and demonstrated by Deutschmann in the fluid from the inflamed joints in 1890, but it can hardly be expected that they should be found in every case. The probabilities are that this was a true case of conjunctival arthritis, the conjunctivæ being inoculated with an attenuation of gonococcus. How the infection took place it is needless to discuss but the probabilities are obvious. Although the synovitis of gonorrhœa is usually the result of the absorption of morbid products from the urethral mucous membrane, there is no reason why the conjunctival mucous membrane should not afford equal facilities. A gonorrhœa need not of necessity be urethral in origin. Mr. R. Clement Lucas[1] has recorded a series of cases which show that ophthalmic rheumatism may attack infants either as an acute arthritis, accompanied by much pain, swelling, and redness, or as a subacute synovitis with effusion. The original ophthalmia may be due to an inoculation from the vaginal discharge of the mother at the time of birth or it may take place accidentally from infected towels or in some similar manner. It is notable that in this case the interval between the appearance of the conjunctivitis and the subsequent arthritis was only a few hours. In the infantile cases the joint affection develops about the end of the second week after conjunctival infection.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

An Analysis of 99 Cases of Inoperable Carcinoma of the Breast treated by Oophorectomy.

A MEETING of this society was held on Jan. 24th, [illegible] Vice-President, being in the chair [illegible] to be worthy of a further trial in certain cases; for though a cure was not to be hoped for the operation in a considerable number of cases had been followed by a marked improvement in the patient's condition, both general and local. Of 99 cases thus treated there was very marked improvement in 23·2 per cent. and distinct though less marked improvement in 13 other cases—that is, 36·4 per cent. of all cases operated [illegible] the operation. If the patients [illegible] old were omitted, of the re[illegible] cent. showed very marked improvement and nine others showed distinct improvement —that is, 41·3 per cent. were benefited by the operation. In successful cases the benefit had been great and was mainly shown in relief from pain, marked improvement in health, diminution or even disappearance of the growth, healing of ulcers, and prolongation of life. In no case had a "cure" resulted with one possible exception. In 32 of the 36 cases which had been benefited by this treatment the [illegible] to the recrudescence [illegible] rded. In one case the [illegible] ough five years had elapsed since the operation was performed. The duration of the improvement was not very often stated but in 15 cases the improved condition of the patient was maintained for more than 12 months and four other patients had good health for four and a quarter years or more. If a growth which was fixed and inoperable before oöphorectomy became smaller and moveable after the operation it was advisable to excise it as soon as the resulting improvement ceased to be definite. The removal should be very freely carried out, as it was probable that a certain number of cancer cells still remained in the immediate neighbourhood of the obvious growth, in the tissues which, though now apparently free, were at one time definitely involved; for in many of the cases in which the disease had completely disappeared after oöphorectomy it had subsequently reappeared in the same situation. The most favourable age of operation was from 45 to 50 years; in relatively young patients it should be given a further trial, but after 50 it was rarely worth doing. The fact that the patient had passed the menopause did not contra-indicate the operation. Secondary growths in the viscera contra-indicated the operation; rapidity of growth or an early recurrence after the primary operation made the prognosis unfavourable. The mortality in this series of cases was high, a little over 6 per cent. It should be noted, however, that the actual cause of death in several of these cases might be regarded as accidental; in two the fatal issue was due to pulmonary embolism and in one to acute mania. The changes which had followed oöphorectomy in the successful cases were still unexplained but it was possible that a morbid variation of the ovarian secretion might be one of the predisposing causes of cancer of the breast and that when the malignant changes had once begun their further development might be favoured by this secretion, and in these cases removal of the ovaries might meet with success if the disease had not already advanced too far. Carcinoma not infrequently developed in a breast which was already the site of chronic mastitis and it might be that there was a connexion between the secretion of the ovary, one or more of the varieties of chronic mastitis, and mammary carcinoma.

---

[1] Transactions of the Royal Medical and Chirurgical Society vol. lxxxii., 1899.

Mr. W. BRUCE CLARKE showed a case of a woman five years after oöphorectomy for inoperable cancer. In 1895 the patient had some bloody discharge from the nipple but no evidence of growth. In 1897 a small nodule was detected and removed and three months later the whole breast was removed and the axilla was cleared out. The growth on section proved to be a duct cancer. In 1898 the posterior triangle became involved and the growth was removed from this situation. In 1899 a further recurrence took place in this situation and the growth was again removed. In November, 1899, the growth had again recurred and involved the right side of the chest. Oöphorectomy was now performed. The pain, which had been a marked feature, rapidly diminished; the growth shrivelled in six weeks and had remained in about the same condition till the present time, some five years after the operation. This was the most successful case that had come under his own observation but in all the cases upon which he had operated some improvement had followed the operation. He never used this method except in inoperable cases.

Mr. J. STANLEY BOYD said that the conclusions which he had drawn from a smaller number of cases coincided with those of Mr. Lett. He was of opinion that the chronic cases were those which gave the best results. In one of his own cases the cancer of the breast had existed four and a half years before the oöphorectomy was performed and the patient had now lived 12 years since the operation. In Dr. Herman's case the cancer had existed for six and a half years before the operation of oöphorectomy and the patient lived 12 years. The cases reported by Watson Cheyne, Beatson, and Edmunds all showed the same chronicity in the primary growth or the greater resistance of the patient to the growth. He did not think oöphorectomy as a primary operation was advisable but he had in two or three instances used the combination of methods—viz., removing the breast and the ovaries—with results which he did not think could have been obtained by the removal of the breast alone.

Mr. JONATHAN HUTCHINSON pointed out how difficult it was to obtain evidence with regard to the duration of carcinoma of the breast. He referred to the case of a most intelligent woman who had a large cancer of the breast in which the growth was stated only to have been present for a week. He then referred to cases in which carcinomatous growths had spontaneously disappeared. He thought that no time-limit could be fixed with regard to the recurrence of carcinoma of the breast and mentioned the case of a woman from whom he had removed the breast and the growth only returned ten years after the removal. The patient died 11 years after the operation.

Dr. G. E. HERMAN said that the paper showed two very important points—viz., that those cases did best when operation was performed about the menopause and that the treatment with thyroid gave beneficial results.

Mr. W. MCADAM ECCLES said that there were three points to which he would allude. First, he attached considerable importance to the nature of the carcinoma, for the variation in the rapidity of growth was considerable; secondly, he thought that much might be learned from the microscopical examination of the ovaries removed; and, thirdly, the examination of the shrunken growth was important and so far as he knew only one such case had been examined. He mentioned a case in which oöphorectomy had been performed for extensive cancer in which all the nodules atrophied except for one or two small points. The patient lived for 26 months after the oöphorectomy and 35 months after the primary growth had been removed. This patient had been the subject of a most violent "nerve storm" after the oöphorectomy but recovered completely in about ten days.

Mr. PEARCE GOULD pointed out the fallacy of the statistical method of collected cases for only the more successful ones were published. His experience of the results of this operation had not been so favourable as that of Mr. Bruce Clarke and he had seen but one case with a striking result. In this instance rapid diminution of the growth took place but the patient unfortunately died from intestinal obstruction. Sections of the atrophied growth showed considerable fibrosis and atrophy of the cell elements. He never felt able to press the operation on a patient whilst the knowledge of the nature of cancer was so uncertain. He had not infrequently seen arrest of the disease without any operation. It was clear that there were physiological means by which the disease could be arrested and he looked forward to the time when these physiological means would be known and rightly applied.

Mr. LETT replied.

MEDICAL SOCIETY OF LONDON.

Discussion on Hæmaturia.

A MEETING of this society was held on Jan. 23rd, Mr. JOHN LANGTON, the President, being in the chair.

Dr. A. E. GARROD, in opening the discussion, said that although the presence of blood in the urine was often a symptom of great diagnostic value the interest and importance which attached to it were almost entirely clinical. It raised no abstruse pathological problems as did the presence in the urine of products of deranged metabolism, with regard to which the kidneys merely played the part of excretory organs, whereas they had their origin in morbid processes behind the renal barrier. In this respect the two very similar conditions hæmaturia and hæmoglobinuria stood in conspicuous contrast to each other. He next dealt with the diagnosis of hæmaturia and said that, as a rule, this gave rise to but little difficulty; occasionally the differentiation of hæmaturia from hæmatoporphyrinuria presented some difficulty if the urine rich in hæmatoporphyrin happened to contain albumin. The microscope would usually serve to remove any doubt. Spectroscopic examination did not supply so delicate a test as was sometimes supposed. If the blood pigment in the urine were always present in the form of oxyhæmoglobin it would be a different matter, but the band in red of methæmoglobin was not nearly so distinct as that of the latter pigment when dilute solutions were examined. The port-wine coloured urine rich in hæmatoporphyrin often showed a pair of absorption bands which closely resembled those of oxyhæmoglobin. Dr. Garrod then dealt with the chemical tests for blood pigment and stated that with the exception of Teichmann's hæmin-crystal test the tests were not so satisfactory as might be wished but they served very well in practice. The ozonic ether and guaiacum test was one of extreme delicacy and the failure to obtain the blue rings, at any rate, afforded most satisfactory evidence of the absence of blood. The microscopical characters of the urine from cases of hæmaturia were then considered and perhaps one of the most definitely diagnostic objects which could be found was the ovum of bilharzia hæmatobia. The presence of tube casts, of renal epithelium, or of fragments of tumours was of the greatest diagnostic importance. He then alluded to a definite group of cases of hæmaturia occurring as an isolated symptom in infants in which the cause was the presence in the urinary passages of crystals of uric acid. A still more important cause of hæmaturia in the early months of life was infantile scurvy and he stated that blood was present in the urine at some period of the disease in the majority of such cases. The hæmaturia in these cases was in no way proportionate to the severity of the disease. In some cases it was an isolated symptom. Passing over such causes as nephritis and renal and vesical calculus Dr. Garrod next dealt with cases of hæmophilia in which hæmaturia had occurred. In other cases hæmaturia was caused by eating rhubarb and this occurred in some cases after a large amount had been consumed, in others when only a small quantity had been taken. He quoted several instances of this form of hæmaturia. Among the rarer forms of hæmaturia the origin of which was quite obscure might be mentioned the cases of idiopathic or congenital hereditary and family hæmaturia, no less than 12 members of one family being affected. The hæmaturia persisted for many years but in some cases it would cease but would recur or increase in a paroxysmal manner. Some obscure cases of hæmaturia had been described in which when an operation was performed no conspicuous lesion was found. In one case reported by Mr. Hurry Fenwick a localised interstitial change was present. Among conditions in which hæmaturia was the sole symptom reference was made to that due to bilharzia hæmatobia which was not very rarely met with in the young men who had returned from South Africa. He then referred to the hæmaturia in cases of parenchymal nephritis and that which occurred in granular kidney, moveable kidney, and lastly to that which occurred in association with prostatic diseases. In conclusion, he referred to the term "renal epistaxis" which suggested that the bleeding might occur from the kidney, as it did from the nasal mucous membrane, without any gross lesion.

Dr. H. E. **BRUCE PORTER** mentioned the case of a man, aged 50 years, who had two attacks of hæmaturia which were definitely connected with the taking of a large quantity of asparagus. In this case no oxalates were present.

Mr. T. H. **KELLOCK** said that he had seen hæmaturia follow a papillomatous growth in the kidney. He mentioned the case of a young man with a tumour in the left kidney. This was removed and it was found that the whole pelvis was filled with a papillomatous growth. Papilloma of the bladder gave rise to more severe hæmaturia than almost any other condition. He did not believe that hæmaturia was a common symptom of renal sarcoma. He was of opinion that a calculus in the cortex of the kidney more often gave rise to hæmaturia than a large calculus situated in the pelvis.

Dr. J. H. **BRYANT** referred [illegible] the cystoscope. In one case [illegible] profuse hæmaturia and enlar [illegible] was found on examination t [illegible] rounded the orifice of the right ureter and so far gave rise to obstruction and hydronephrosis. The patient made a complete recovery after the removal of the growth from the bladder. In a second case blood could be seen oozing from the left ureter. Bacteriological examination was also of value in such cases.

Mr. R. H. J. **SWAN** referred to the value of the cystoscope and the separator. Even in cases of profuse hæmaturia it was often possible to make a diagnosis in a fluid medium in the bladder which was not quite clear. A rapid examination often sufficed to make the diagnosis obvious. He said that in tuberculous cystitis hæmaturia might be the only symptom. He related the case of a small boy whose bladder had been opened under the supposition that a papilloma was present. Nothing was found but by subsequent examination with the cystoscope a tuberculous condition was seen. He thought that hæmaturia as the only symptom in cases of enlarged prostate was very rare.

Dr. F. J. **POYNTON** referred to hæmaturia occurring in infants suffering from scurvy without any other symptoms Hæmorrhage from the kidney occurred in cases of malignant endocarditis, partly due to infarcts but also due to a toxic nephritis. In one instance in which he had injected a cat with a virulent growth of streptococci the animal had developed a nephritis from which it completely recovered and when killed subsequently the kidneys were found to be perfectly normal.

The **PRESIDENT** referred to the rough clinical tests for the diagnosis of the source of hæmorrhage—viz., that when intimately mixed with the urine the blood probably came from the kidney or ureter when following the passage of clear urine from the bladder, and when at the commencement of micturition as coming from the urethra. He referred to the case of a man with all the symptoms of stone in the kidney. He explored the kidney but was unable to find any calculus. The man made a complete recovery and was perfectly well 18 years later. He thought that hæmaturia was more commonly the result of small calculi than of large ones.

Dr. **GARROD** replied.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Instruments.—Bony Deposits following Injury. — Cerebellar Abscess. — Acute Labyrinthitis. — Typhoid Fever.

A MEETING of this society was held on Jan. 19th, Dr. **JAMES BARR**, the President, being in the chair.

Dr. W. **BLAIR BELL** exhibited and demonstrated the use of the following instruments: (1) Combined Peritoneum Forceps and Wound Retractor; and (2) Complete Infusion Apparatus, with improved Venous Cannula.

Mr. **ROBERT JONES** and Dr. **DAVID MORGAN** presented an Analysis and Radiographic Illustrations of 16 cases of Bony Deposits following Dislocation of the Elbow-joint under their observation. These deposits had followed simple dislocation, unaccompanied by fracture, and were not associated [illegible] ffered from [illegible] occurrence [illegible] vith callus. [illegible] n of these bony deposits. A series of radiographic lantern slides depicted their growth, from slight shadows to dense bony formation. The diagnosis and the prognosis were discussed and microscopic slides were shown to demonstrate their true bony nature as distinct from calcareous changes.

Mr. W. T. **CLEGG** read notes of a case of Cerebellar Abscess which occurred as the result of acute ear trouble. The clinical history of the case was given and the differential diagnosis between temporo-sphenoidal and cerebellar abscess was discussed. An operation had been performed but without relief to the patient. At the necropsy a large abscess was found in the right lateral lobe of the cerebellum, the infection having travelled from the ear along the sheath of the auditory nerve. There was no meningitis.

Mr. **CLEGG** also related a case of Acute Labyrinthitis in a child, two years and eight months of age, in which the symptoms closely resembled those of meningitis. After recovery deafness persisted. There had been no discharge from the ear.

Dr. **NATHAN RAW** read a paper on Some Points in the Diagnosis and Treatment of Typhoid Fever based on an observation of 362 cases treated in hospital during the last 16 years. He referred in detail to the great difficulties in diagnosis which many cases presented in the early stages of the disease and discussed the value of Widal's reaction as an aid to the practitioner Hæmorrhage and perforation were the two most formidable complications and a careful *résumé* of the symptoms of perforation of the intestine was given as it was highly important to be able to diagnose its immediate onset so that prompt operative measures might be adopted. In his opinion the treatment of the future would be directed towards reducing the virulence of the bacilli and the onset of toxæmia on the lines suggested by Dr. A. E. Wright or by the introduction of a serum. The cold or continuous bath treatment undoubtedly in other countries gave better results than any other, but he believed it would be some considerable time before it was generally adopted in this country in the treatment of typhoid fever.—Dr. W. **CARTER** considered Brieger's suggestion of feeding patients suffering from typhoid fever with pure peptones good and he had carried it into practice for many years. Commenting upon Widal's reaction, he mentioned two cases in which it proved misleading. —Dr. W. B. **WARRINGTON** considered that even when much care was taken the serum reaction was not devoid of ambiguity and the observer was from time to time left in doubt as to the positive or negative nature of the reaction.—Dr. N. E **ROBERTS** was of opinion that the mortality of enteric fever in Liverpool, when treated in hospital under modern conditions, would average about 12 per cent. He based this [illegible] ase of close upon 2500 cases treated at the city [illegible] of this disease was greatly [illegible] under treatment, and as [illegible] aid that he had never lost a nurse or any member of the hospital staff from enteric fever at the Grafton-street or Parkhill Hospitals since he joined those institutions in 1892.—The PRESIDENT, Dr. J. HILL ABRAM, Dr. T. R. BRADSHAW, Dr. A. G. GULLAN, Dr. C. J. MACALISTER, Dr. R. S. ARCHER, and Dr. R. J. M. BUCHANAN also took part in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on Jan. 6th, Dr. H. C. EARL, the President, being in the chair.

Professor O'SULLIVAN (for Dr. ROY S. DOBBIN) showed specimens from a case of Extensive Anæmic Infarction of the Liver. The case was one of puerperal eclampsia, with jaundice. A large gall-stone was impacted in the upper end of the gall-bladder. The smaller branches of the hepatic artery showed an extensive degeneration of the walls, commencing in the muscle cells of the middle coat, and accompanied by a similar change in the walls of groups of capillaries in the neighbourhood of the branches of the artery. The degenerated material took on Weigert's fibrin stain deeply and gave none of the amyloid reactions. Hyaline thrombi were present in some of the arteries. The walls of the hepatic and portal veins were healthy. Some of the portal veins inside the infected areas were thrombosed.

The PRESIDENT and Mr. R. C. B. MAUNSELL showed an Endothelioma of the Uterus.—Professor O'SULLIVAN expressed the opinion that the diagnosis was not justified in the present state of knowledge in regard to endotheliomata unless the transition from the ordinary endothelium of the lymph space to the tumour endothelium could be established.—The PRESIDENT agreed with Professor O'Sullivan's remarks and admitted that there were many parts of the tumour from which nobody could possibly establish a diagnosis.

The PRESIDENT showed a large Myoma of the Rectum which was removed by Dr. F. M. Golding, of Headford, from a woman during parturition. The tumour measured three and a half inches in its longest diameter by two and a quarter inches in its shortest. It presented some patches of calcification near its surface. It was attached to the wall of the rectum by a thin membrane.—Dr. R. TRAVERS SMITH asked if there was any possibility of it being a uterine tumour which had found its way out per rectum.—The PRESIDENT said that he did not think it was a uterine myoma because he believed that if a patient had had a myoma like that ulcerating into her bowel she would have complained about it. Dr. Golding had also given a distinct history of its having a membranous attachment which would not have been present if the tumour had ulcerated its way into the rectum.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on Jan. 17th, Sir William J. Collins, the President, being in the chair.—Dr. J. G. Garson read the notes of a case of a Double Fracture of the Right Clavicle which resulted in a civil action for damages.—The President recalled Sir Robert Peel's fatal injury which was too painful for examination.—Dr. J. Howell Evans insisted on the importance of the two fulcra upon which the clavicle rested.—Dr. Garson also gave a Demonstration on the Development of Invisible Finger-prints. He suggested that vital evidence was often lost by disturbing the environment of a crime before it had been skilfully investigated.—Mr. A. Douglas Cowburn opened a discussion on the Law relating to the Criminal Responsibility of the Insane. The question was primarily one for the jury. It was frequently impossible to apply the knowledge-test of right and wrong, as required by the answers of the judges in 1843. Again, men undoubtedly insane had been convicted as criminals and although substantial justice was obtained by the intervention of the Home Office such methods of trial were undesirable. The laxity of medical definitions and hypotheses led lawyers to be firm in adhering to their rules. "Moral insanity" rarely existed without intellectual derangement and many crimes alleged to be the result of sudden impulse had been, in fact, carefully planned out. Medical evidence must be more definite and precise than was the usual case. Any change of rule must have wide moral support and must not make it easier for criminals to escape unpunished. It was better to leave "insanity" undefined and to agree that no act done by a person in a state of insanity should be punished. The vast majority of cases presented little diagnostic difficulty to the expert alienist and to him the decision must be left. The law must apportion its standard of responsibility to each individual case. Criminals—i.e., those convicted of one of the 82 indictable offences—might thus be classified into five relative groups: (1) the professional criminal; (2) the habitual criminal with a bad police record; (3) the occasional criminal, the victim of temptation; (4) the insane criminal, who should be exempt from punishment; and (5) the weak-minded criminal, who should receive medical treatment rather than punishment. The foregoing principle actually obtained in the convict cell but not in the courts.—Dr. James Scott regarded the recommendation of the jury "to mercy" as to some extent a recognition of the class of the "feeble-minded."—Dr. Ernest W. White recognised a slope and not an angle in the gradation of sanity to insanity; further, one fixed delusion proved general mental disease. Both he and Dr. T. Outterson Wood maintained that each case must be considered individually as it arose.—Mr. John Troutbeck expounded Jeremy Bentham's "Theory of Rewards and Punishments."—The President, in concluding the discussion, insisted that the test of guilt was not within the sphere of cognition but that of volition. Wundt had, at the close of his theory of psycho-physical parallelism, allowed that conduct was determined by personality; motives arose externally, causes internally. There was, and must be, some mental calculus in considering these problems involving responsibility. The questions at the back of our minds were, he submitted, Had the prisoner the power of choice? Could he act upon it? Were his choice and act in accordance with the general moral sanction of the time and place in which he lived and with the legal sanction prescribed by the legislature?

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Jan. 17th, Dr. T. Vincent Dickinson, the President, being in the chair.—Dr. J. D. E. Mortimer read a paper on the Anæsthetisation of Children. After referring to various practical details he pointed out that the prone or latero-prone positions were apt to embarrass the breathing, especially in rickety children, and that in cases of empyema the child should never be turned on the unaffected side. In giving chloroform the induction of anæsthesia should be gradual but not too prolonged and there ought to be a free admixture of air. The lint, if such be used, should never be applied closely to the face; by so doing it was certainly possible to anæsthetise or rather narcotise a patient, using a very small amount of chloroform, but the method was both inconvenient and dangerous. Coroners and juries appeared to be under the impression that the amount of chloroform used was a measure of the amount inhaled and that the production of anæsthesia with a small quantity indicated a skilful administration, whereas the reverse was often the case. —Mr. A. F. Penny read a paper on two cases of a Hitherto Unrecorded Complication of Pregnancy. The first case was seen by him in consultation with Mr. C. A. Morris and subsequently, on the removal of the patient to the Grosvenor Hospital, by the other members of the staff there. The second case was seen by Mr. Morris and also by Dr. Seymour Taylor. Both patients recovered, although they presented very alarming features and both miscarried, one at six and a half months and the other within a fortnight of full term. The prematurely born child survived for three hours; the other child had to be delivered by forceps and was born dead with the cuticle peeling. The two cases simulated typhoid fever very closely. In the first of the two the blood was examined twice for Widal's reaction but with a negative result. In this case the illness began with a rigor on June 25th and the woman's temperature was found to be 103° F. There was constipation for the first week but afterwards the bowels were relaxed and the stools were distinctly typhoid in character. Two days before she miscarried the temperature rose to 104·8° and on July 7th, just before labour pains began, it was 103·6°. Immediately labour started it dropped to 97° and remained subnormal afterwards for two or three days. There was no further pyrexia. In the second case there was constipation throughout. When first seen by Mr. Penny on July 2nd the woman complained of very severe pain in the upper part of the right lumbar region. The abdomen was very distended and tender and on the right side the colon was enormously distended and overlapped the enlarged uterus. Her temperature varied between 100° and 102° until July 8th, when it rose to 103·6°. On July 10th, an hour or two before labour pains began, it dropped to 101·2°. Immediately the pains commenced the temperature was found to be 97°. It remained subnormal for three days, when it reached the normal standard and there was no further pyrexia. Mr. Penny could offer no explanation of the phenomena.—Dr. J. Anderson read a paper on the Treatment of Various Diseases by Light and gave details of several cases in which he claimed that a successful result had been obtained by this means. The patients suffered from gout, rheumatism, various neuralgias, insomnia, and anæmia.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—The annual meeting of this society was held in Manchester on Jan. 20th, Sir William J. Sinclair, the President, being in the chair.—The following officers were elected:—President: Dr. D. Lloyd Roberts. Vice-Presidents: Sir William Sinclair, Dr. W. Walter, Mr. Owen Bowen, Dr. Arthur J. Wallace, Dr. J. B. Hellier, Dr. A. C. F. Rabagliati, Dr. John W. Martin, and Mr. Percival E. Barber. Honorary treasurer: Dr. E. Octavius Croft. Honorary general secretary: Dr. W. E. Fothergill.—Mr. G. A. Hawkins-Ambler showed two specimens of Apoplexy of the Ovary. The first was from a patient, aged 41 years, who had violent abdominal pain during influenza two weeks after a profuse menstrual period. The enlarged uterus emitted a sanious discharge. The left ovary was turned into [illegible] size of a hen's [illegible] a chocolate-[illegible] was cystic and adherent. The second specimen was from a patient, aged 35 years, who during the previous year had had various attacks of pelvic peritonitis. An ovoid cyst of the size of an orange was found adherent to the uterus on the left, to the rectum, and to the colon. It was filled with blood clot and fibrin and represented the left ovary.—Dr. Hellier described two cases illustrating the production of Uterine Souffle. One was an instance of uterine myoma of the size of a three months' pregnancy which caused a loud bruit together with a palpable thrill. After removal of the uterus injection showed the presence of a large artery and a large venous sinus on its right side. The other case was one of retroperitoneal sarcoma which pushed the uterus up so as to form a visible prominence on the abdomen extending three and a half inches above the pubes. Over this there was a soft souffle which disappeared after the enucleation of the tumour.—The President (Dr. Lloyd Roberts) showed a Liver Enlarged by Metastatic Deposits, the primary lesion being cancer of the pancreas. A lobe of the liver, divided from the main mass by a deep sulcus, extended into the right side of the pelvis. This caused a difficulty in diagnosis, as during life the condition suggested the presence of a separate tumour of pelvic origin co-existent with enlargement of the liver.

LARYNGOLOGICAL SOCIETY OF LONDON.—At the annual meeting of this society held on Jan. 13th the following officers were elected for the year 1905:—President: Mr. Charters J. Symonds. Vice-Presidents: Dr. W. Milligan, Dr. F. Willcocks, Dr. J. B. Ball, and Dr. G. William Hill. Council: Dr. L. H. Pegler, Dr. J. Walker Downie, Dr. P. McBride, Mr. W. R. H. Stewart, Sir Felix Semon, and Dr. E. Furniss Potter. Honorary treasurer: Mr. H. B. Robinson. Honorary librarian: Dr. StClair Thomson. Honorary secretaries: Mr. P. R. W. de Santi and Dr. H. J. Davis.—At the ordinary meeting the following cases and specimens were shown:—Dr. StClair Thomson exhibited a case of Epithelioma in a man, aged 50 years, in whom laryngo-fissure was performed and there was no recurrence after six months. He also showed a boy, aged 14 years, in whom Tracheotomy was performed for Extreme Stenosis, the larynx being extensively ulcerated and the cords fixed in the middle line. There was marked improvement after the operation and the diagnosis rested between tubercle, lupus, and congenital syphilis.—Mr. de Santi showed for diagnosis a case of Swelling of the Left Arytenoid Region in a woman, aged 35 years. The diagnosis was considered to be either tubercle or malignant growth.—Dr. H. Tilley showed a case of Tracheal Obstruction.—Sir Felix Semon showed two cases: (1) Pharyngeal and Laryngeal Nystagmus in a case of probable tumour of the pons; and (2) a case of Inflammatory Œdema of Obscure Origin, affecting the posterior part of the larynx, in a man, aged 45 years.—Dr. H. W. Fitzgerald Powell showed a case of Epithelioma of the Palate, Tonsil, Tongue, and Cheek and suggestions were invited as to the effect of the x rays in such a case. The opinion generally expressed was that the x rays would not be of much value in such cases.—Mr. F. H. Westmacott showed a case of Ulceration of the Soft Palate which had been operated upon frequently yet was perpetually recurring. It was not influenced by iodide of potassium.—Mr. O. A. Parker showed a case of Symmetrical Enlargement of the Thyroid.—Dr. Smurthwaite exhibited a beautiful series of Paintings in Oil indicating Diseases of the Throat and Larynx.—Dr. D. R. Paterson showed a Pair of Laryngeal Forceps for use by the direct method.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Jan. 20th, Dr. J. S. Risien Russell, the President, being in the chair.—Dr. Lewis A. Smith opened a discussion on the Management of a case of Glycosuria. He advised that a patient seeking advice who was passing sugar in the urine should not be told that the condition was diabetes. Though advances had been made in the knowledge of the parallel conditions of glycosuria yet they were in the dark now as formerly as to the cause of the condition. Various pathological conditions of various organs seemed causal of glycosuria; it probably was the case that some loss of balance of function of the body as a whole resulting from disease of the brain, the pancreas, the liver, or the kidney could, and did, so alter the metabolism that the sugar was unburned and passed from the body as sugar. Where exactly this sugar was transformed was unknown. He said that the only sure and true test for sugar was fermentation. Stress was laid on the fallacies common in chemical testing and he illustrated those remarks by the anxiety caused sometimes when on adding the perchloride of iron solution to a urine containing sugar a red reaction resulted. Yet that reaction was due to salicylates taken by the patient and not to the presence of diacetic acid. The presence of even a large quantity of sugar in the urine was not of itself warrant for a grave prognosis, for eight years ago he saw a man who had dry gangrene of two toes with much sugar in the urine who recovered, grew fat, and worked hard. The presence of diacetic acid, a resultant of autoproteid metabolism, was the best guide as to the severity of a case and indicated the near approach of coma. For this sodium bicarbonas should be given in doses of about two ounces daily. In the beginning of attending a glycosuric patient care should be taken not to change the previous diet suddenly, for deaths had been recorded apparently as a consequence. Drugs should be avoided until the full reduction of the sugar had been attained by diet alone, then drugs might be given.—A discussion followed, to which Dr. Lewis Smith replied.

ROYAL MEDICAL SOCIETY, EDINBURGH.—A meeting of this society was held on Jan. 13th at which Dr. John Thomson delivered an address on Congenital Pyloric Spasm. He began by going into the history of the subject, stating that before 1896 very few cases had been described but that after that year the number of cases had steadily grown. He then discussed the pathology of the condition and its causation. In this connexion he gave two theories—the first, that it was due to a simple primary hyperplasia and the second, to which he himself leaned, that it was due to a secondary overgrowth following overwork. He next treated the question of the symptoms and diagnosis, mentioning the explosive vomiting, the absence of the signs of dyspepsia, the smallness of the motions, the general emaciation, and the prominence of the stomach and pyloric thickening. After describing the course of the disease, he went fully into its treatment, both medical and surgical, mentioning such operations as pylorectomy, stretching, and gastro-enterostomy. In the course of his address Dr. Thomson exhibited slides of numerous cases.—Dr. A. C. Geddes moved, and Dr. L. S Milne seconded, a vote of thanks.—Dr. H. D. Shepherd then read a dissertation on the Evolution of the Limbs. He prefaced his paper by giving an account of the line of the development of the vertebrates, saying that the first appearance of a well-marked limb occurred in the suaropsida. He then selected the newt, the frog, and a mammal as representing three great stages in the development of the limbs. Next he compared the hind limbs in these three groups, taking the newt first and pointing out the absence of torsion in the femur. Of the frog he said that here a bending of the head of the femur, a sloping of its condyles, a rotation of the ankle, and other advantageous changes could be detected. He concluded by going fully into various interesting points of mammalian comparative anatomy.—Mr. D. M. Barcroft proposed, and Mr. T. B. Johnston seconded, a vote of thanks.—Dr. J. M. Graham then read notes of three cases of Hysteroparalysis.

BURNLEY AND DISTRICT MEDICO-ETHICAL ASSOCIATION.—A clinical meeting of this society was held on Jan. 5th, Dr. A. M. Sinclair being in the chair.—Dr. A. Donald read a paper on Puerperal Septic Infections. He laid especial stress upon injuries to the perineum and to the vagina as causes of sepsis. He had found the power for repair of these injuries to be defective and in many instances the wounded part was covered with a thin grey slough. He strongly advocated surgical precautions in all midwifery cases; not that such precautions would entirely obviate septic dangers but that they would materially lessen them. For treatment he deprecated curetting and hysterectomy—in the former case the danger of pushing vaginal septic material into a possibly otherwise healthy uterine cavity seemed to be great and in the latter to remove a probably unoffending organ seemed a crime. —A discussion followed in which Dr. J. Mackenzie referred to his earlier and his later experiences and remarked that many of the younger practitioners had no knowledge of puerperal sepsis.—Dr. R C. Holt called attention to the remarkable statistics of some of the older practitioners who could show lists of cases attended where the death-rate was not 1 in 1000 and remarked upon their practice as he had seen it He thought that the too free use of the forceps and the practice of Credé's method of expelling the placenta were responsible for many evils.—Dr. J. Gardner drew attention to the differences between women in towns and women in the country, more especially with regard to vaginal secretions.—Dr. G. S. Pullon, Dr. J. S. Wilson, Dr. W. Bird, and Mr. J. Hodgson also related their experiences.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held at the Medical Institute, Birmingham, on Jan. 18th, Dr. E. W. Wood White, the President, being in the chair.—Mr. H. G. Barling showed (1) a patient from whom he had successfully removed a Tumour of the Cerebrum; (2) a man who had been the subject of Migraine of many years' standing and who was successfully treated by the fixation of a moveable kidney; and (3) a specimen of Advanced Hydronephrosis in a Moveable Kidney removed from a woman, aged 50 years, who had suffered pain more or less for 20 years but more severely during the last 12 months. The other kidney was also freely displaced downwards but was not hydronephrotic.—Mr. L. P. Gamgee showed (1) a woman, aged 51 years, who for seven years had suffered constantly from very severe headaches which had resisted all ordinary forms of treatment (fixation of a right moveable kidney had resulted in complete disappearance of the headaches); and (2) a large Hydronephrosis removed from a woman, aged 40 years. The patient had suffered from a moveable kidney for 20 years and the hydronephrosis was apparently a direct result of the mobility. —Mr. Barling read a paper on Renal Mobility and its Treatment.

BRISTOL DISPENSARY.—The annual meeting of the subscribers to the Bristol Dispensary was held on Jan. 13th. The report stated that during 1904 the patients numbered 10,556, being a slight decrease compared with the previous year. The financial statement was satisfactory and showed a favourable balance of £10.

PHYSICAL VOICE-TRAINING SOCIETY.—A meeting of this society will be held on Wednesday, Feb. 1st, at 5.30 P.M., at the Medical Society's rooms, 11, Chandos-street, Cavendish-square, London, W. The Lord Bishop of Bristol will take the chair and the speakers will include Canon Barker, the Principal of King's College, and Dr. V. H. Wyatt Wingrave. The honorary secretary is Miss C. D'Orsey. Those who attended the breakfast given by that lady at Oxford on July 29th, 1904, and the subsequent meeting and others who are interested in the subject may be reminded that further particulars of the objects of the society will be found in THE LANCET of August 13th p. 502.

Reviews and Notices of Books.

An Atlas of Human Anatomy. By CARL TOLDT, M.D., assisted by Professor A. DALLA ROSA, M.D. Translated from the third German edition by M. EDEN PAUL, M.D. Brux. Sixth section: G, Neurology; H, the Organs of the Senses (Figs. 1124 to 1505 and Index. London and New York: Rebman. 1904. Pp. 746-956 and Appendix (pp. 30). Price 16*s.* 6*d.* net.

THIS handsome volume completes the translation of Professor Toldt's Atlas of Human Anatomy adapted to English and American international terminology. Five plates are devoted to diagrams of the structure of nerve fibres, cells, and terminal sensory organs. Figures 752 to 808 are devoted to the central nervous system, gross anatomy, development, and excellent schemata showing the connexions of the parts of the central nervous system one with another and with adjacent sense organs largely make up this part of the work. All the sketches are bold, clearly drawn, and every part is duly labeled, so that any student glancing over these pages can readily refresh his memory. The transverse, horizontal, and other sections of the brain are admirably drawn, while the diagrammatic representations of the continuation of the several tracts of the cord into the brain are particularly good, for after all it is a knowledge of the connexions between the several parts of the nervous system which is useful to the physiologist and the physician. We may refer particularly to Figs. 1225 and 1226 showing the course of the continuation of the posterior column of the cord, and Figs. 1227 and 1228 depicting the connexions of the eyeball and its muscles with the brain and medulla.

To the peripheral nervous system (Figs. 1240-1325), nearly 100 figures are given, many of them occupying a whole page. The sketches of the distribution of nerves to the viscera are particularly good and so are the delineations of the nerves to the hand, in fact, the plates in this part strike us as amongst the best in the whole Atlas. The sympathetic nervous system is dealt with in Figs. 1326 to 1333 and most excellent plates they are. The rest of the work is devoted to the organs of sense, the major part to the eye (Figs. 1334-1403), including its anatomy, structure, and development; the ear (Figs. 1404-1468); the nose (Figs. 1469-1481); while Figs. 1482 to 1505 are devoted to the skin.

In the notes by the translator in the Appendix a concise but lucid sketch is given of the newer views on the structure of the central nervous system. Numerous annotations occur, showing the differences between German and English nomenclature—e.g., cardiac plexus. English anatomists make a distinction between a superficial and a deep cardiac plexus which is ignored by Professor Toldt. The references regarding different terminology are chiefly to Quain and MacAlister.

Altogether the work is excellently translated, the printing is good, and the plates and figures are clear and distinct and well chosen. We think that this part will prove fully as useful as any of its predecessors. We congratulate both authors and publisher on the success of their endeavour.

The Chief Operations of Ophthalmic Surgery: A Practical Guide for Students. By HAROLD B. GRIMSDALE, M.B., B.C. Cantab., F.R.C.S. Eng., Assistant Ophthalmic Surgeon to St. George's Hospital; Surgeon to the Royal Westminster Ophthalmic Hospital. London: *The Medical Times.* 1904. Pp. 144. Price 5*s.*

THE operations given in detail in this little work include those for strabismus, ptosis, entropion, ectropion, tarsorrhaphy, lacrymal obstructions, enucleation, evisceration, cataract, glaucoma, iridectomy, peritomy, and corneal cornea. The author has had considerable experience in the wards and operating theatres of St. George's and the Royal Westminster Ophthalmic Hospitals and therefore writes with authority. The account given of each operation is sufficiently accurate, though in giving three or four methods it would have been more serviceable to the student if the author had indicated the particular conditions rendering one plan superior to another. It is convenient to the student to have in compact and portable compass the various proceedings that have been suggested for the relief of certain diseases, defects, and deformities but we demur to the statement made in the introductory chapter that "most text-books on ophthalmology give up a very small part of their space to the somewhat important branch of operative surgery." We have looked at several of the recently published treatises, such as those of Juler, Berry, Norris and Oliver, Fuchs, Swanzy, Ball, and others, and find that many pages in each of these works are devoted to operative proceedings, though the accounts are distributed under different headings and are not collected together as in Mr. Grimsdale's treatise. In the account of Mules's operation it is stated that in "something like 20 per cent. of all cases the central stitch gives way and the globe emerges." Surely this estimate must include those cases in which the operation has been performed by unskilful hands. The failure is almost certain if too large a glass or silver globe is inserted, whilst if all traction is avoided it is generally successful. A small globe gives a very good *point d'appui* for a well-made artificial eye. The description of Maxwell's operation for shallow socket is very well given. Kronlein's operation for the removal of the outer wall of the orbit might have been introduced. The woodcuts, though intelligible, are very coarse; the text deserves to be illustrated better.

An Account of the Tapeworms of the Genus Hymenolepis
Parasitic in M
of the Dwarf
By BRAYTON
No. 18. Sep
Printing Office. 1904. Pp. 131.

THIS publication contains a full account, from both the zoological and medical aspects, of the three representatives of the tapeworms of the genus hymenolepis, parasitic in man. The hymenolepis nana, the dwarf tapeworm of man and rats, is of small size and has no doubt been frequently overlooked owing to the diagnosis of its presence being dependent on the discovery of its eggs microscopically. About 100 cases have been reported in man. It was first described in 1845 by Dujardin in rats; then in man by Bilharz at Cairo in 1851. The Italian investigations showed that when the eggs are swallowed by white rats, the embryos hatch, bore into the intestinal villi, become transformed into an intermediate stage of cercocysts, and finally fall into the lumen of the intestine to become adults. A similar development is presumed to occur in man, although it is possible that some portion of the process of development both in man and rats may occur in some intermediate host such as an insect; this, however, is not yet determined.

The large majority of cases occur in male children between the ages of five and ten years. More cases develop in cities than in the country. Bad hygienic surroundings are especially liable to cause infection. The largest number of cases has been reported from Italy; and next to Italy from Columbia. The ileum is the part infected and in number the worms may vary from one to several thousand. Other parasites again may be present at the same time, whilst the infection may last from two months to two and a half years, perhaps even to five years or even longer. Clinically the symptoms are usually slight and may be absent altogether, although severe ones, such as persistent diarrhœa and epileptiform attacks, occasionally occur. The most frequent symptoms are abdominal pain with or without diarrhœa, convulsions of various sorts (frequently epileptiform), headache, and strabismus. Nasal and anal pruritus common in cases of other tapeworms are rare. Nervous symptoms seem to occur more especially in those patients predisposed to nervous disease. The local pathological changes are slight. The diagnosis rests on the discovery of the eggs.

In making the necessary research a very small particle of the fæces to be examined has simply to be rubbed up with a drop of distilled water on a glass slide, covered with a cover glass, and examined with a moderately high power. The eggs are very transparent so that they are likely to be overlooked unless care is taken. The characteristic appearance of these eggs is the presence of two distinct membranes, an inner one closely investing the embryo with filaments attached to its poles and an outer separated from the inner by a considerable intervening space. The treatment is by male fern which may have to be repeated several times. Prophylaxis consists in the avoidance of everything favouring the entrance of eggs into the mouth, the destruction of rats and mice, and the protection of food from contamination by their excreta, whilst children must be carefully prevented from putting into their oral cavities all the various objects which, soiled by these excreta, may carry the eggs.

The second worm, the hymenolepis diminuta, or flavopunctate tapeworm of man and rats, occurs by means of an intermediate host, the common meal moth being the most frequent. It gives rise to practically no symptoms and is diagnosed by the discovery of its eggs in the fæces. Here the outer membrane of the eggs has a radial striation, distinguishing it from the last, whilst the intermediate substance between the two membranes is more prominent, and there are no filaments at the poles of the inner membrane. In the treatment a simple cathartic is all that is necessary and the avoidance of all the various insects acting as intermediate hosts. The hymenolepis lanceolatus of geese and ducks has been recorded but once from man.

LIBRARY TABLE.

Électricité Médicale. By Dr. H. GUILLEMINOT. Paris: G. Steinheil. 1905. Pp. xii. + 656. Price 10 francs.—We think that an English translation of this book would well repay any trouble that it entailed. It is essentially practical and many interested in medical electricity would be only too glad to have a book such as this, which gives all the latest ideas of our French colleagues on the subject, without the trouble of translating it for themselves. The work is divided into three parts, the first of which is devoted to electro-physics. Apparently the time has not yet come when the preliminary training of medical men in electricity is such that this section can be dispensed with in works on medical electricity. The second part relates to the physiological effects of the various forms of electrical energy on living tissues. It includes the action of the different light rays which have taken such an important place in physical therapeutics. The action of the static machine current and currents of high frequency are dealt with very fully, as would naturally be expected in a book coming from a country where these agents are much more extensively used than they are here. The third section extends over half the volume and deals with the practical applications of electricity in diagnosis and therapeutics. This, of course, is the part of most interest to medical men. A novel feature of this section is the author's method of describing the treatment of each organ of the body under a separate heading. The part relating to diseases of the skin is worthy of special mention and will well [illegible] time [illegible] en to its study. The book can be thoroughly commended. The publishers' work has been very satisfactorily done, the volume being of a convenient size and the printing and illustrations particularly clear.

The Transactions of the Hunterian Society, 1903–1904. Eighty-fifth Session. London: Headley Brothers. 1904. Pp. 85.—In addition to the usual lists and report about the society, which latter shows a satisfactory financial position, these Transactions contain Dr. J. F. Woods's oration on the Psychic Side of Therapeutics; Dr. W. Hale White's lecture on Some Clinical Considerations concerning Certain of the Rarer Forms of Enlargement of the Heart; the second Hunterian lecture on Pain: its Importance in Diagnosis and Tendency to Mislead, by Mr. A. A. Bowlby; and Dr. Paul C. Franze's paper on the Physiological Action of the Nauheim Bathing Wells and the Indications for their Use, chiefly in Circulatory Disorders. The reports of the cases and specimens shown on the clinical and pathological evenings are very interesting.

The Food of the Future: a Summary of Arguments in Favour of a Non-flesh Diet. By CHARLES W. FORWARD. With a Preface by ERNEST BELL. London: George Bell and Sons. 1904. Pp. 128.—In this little book arguments in favour of a non-flesh diet are set forth. In the preface Mr. Bell remarks that "in reality force of custom, appetite, and the desire for sensual indulgence is the only 'reason' for the inhuman habit [of flesh eating], if one may use the word where no reason enters at all." The book is stated to be for those "who are ready and waiting to climb off the purely physical sensuous plane, who long for some higher ideal than seems to satisfy the average man. It is to these the book may be helpful in showing that in following their better natures they have reason, and humanity also, on their side."

Home Nursing and Hygiene Handbook. By J. WALLACE ANDERSON, M.D. Glasg., F.F.P.S. Glasg., and GEORGE H. EDINGTON, M.D. Glasg., F.F.P.S. Glasg. Glasgow: St. Andrews Ambulance Association. 1904. Pp. 156. Price 1*s.* net.—This work is the official text-book of the St. Andrews Ambulance Association which is the Scottish organisation corresponding to the English St. John Ambulance Association. It gives plain and simple directions for home nurses, together with the elements of hygiene and various surgical information for which Dr. Edington is responsible. The book should be found of great use to those for whom it is intended and we are glad to see a note describing how to make coffee by simple infusion in the same manner as tea is made. There is one slip which should be corrected in a future edition, and that is on p. 85 where atmospheric air is spoken of as "not one of the elements ...... but a compound body." The word "compound" placed in antithesis to the word "element" gives the uninstructed person the idea that air is a chemical compound. The substitution of the term "mixture" would be advantageous.

The Public Schools Year-book, 1905. London: Swan Sonnenschein and Co. Pp. 622. Price 2*s.* 6*d.*—This book of reference gives particulars of all public schools—i.e., it is limited, "with a few carefully weighed exceptions, to such public schools as were connected with the headmasters' conference." A "Girl's School Year-book" is promised to appear during the year. In the book now before us will be found particulars of the various schools, together with information concerning the services, the medical profession, and the musical profession. Appendix X. deals with agriculture, horticulture, and with colonial openings for public school boys. Lists of preparatory schools are given but these are "not official or in any way exhaustive," and besides the matters which we have mentioned there is a variety of other information which must be of great use to all parents or guardians.

The Schoolmaster's Year-book and Directory, 1905. London: Swan Sonnenschein and Co. Pp. 1058. Price 5*s.* net.—The above-mentioned work covers wider ground than the preceding book, for its sub-title is "A Reference Book of Secondary Education in England and Wales." It contains a vast amount of information upon the subjects which are included under the comprehensive term "education" and its editor deserves every credit for the pains which he has evidently taken to compile a full, careful, and up-to-date account of educational matters and establishments and of subjects connected therewith.

Diaries.—Messrs. W. H. and L. Collingridge of the *City Press* have sent to us "The City Diary" (price 1*s.*). It is a useful desk companion, is of a handy size, gives three days to a page, is interleaved with blotting-paper of good quality, and lastly, contains a miniature City encyclopædia. The information afforded in the prefatory section appeals to, and will be found of practical utility by, every citizen who takes any interest at all in the affairs of the one square mile. The "Diary" gives, for instance, a complete list of members of the corporation, ranged alphabetically, and also according to their wards; of the City churches, with the names of the rectors, curates, organists, and other officials; of the City companies, with the names of the clerks and the situation of the halls; and of the various municipal, social, and parochial institutions that have their headquarters in, or are in any way associated with, the City. In a word, therefore, the annual is a work of reference as well as a diary pure and simple.—Messrs. Rudall, Carte, and Co. have sent us their useful Professional Pocket Book or Daily and Hourly Engagement Diary for 1905. The diary, which is contained in a neat leather case, is divided into three sections of four months each. Although primarily intended for the use of musicians any professional man or woman will find it very handy. Besides the diary there are a calendar containing the usual information and a set of blank pages for memoranda.

JOURNALS AND MAGAZINES.

The Field Naturalist's Quarterly. London: Simpkin, Marshall, and Co. Edinburgh: G. A. Morton.—The December number of this quarterly, which is only just to hand, completes the third volume of a magazine which, though it appeals specially to field naturalists, contains articles of much interest to the general reader. The editor, Dr. Gerald R. Leighton, commences a series of articles entitled, Modern Studies in Heredity, and Mr. F. G. Aflalo writes in his well-known pleasant style on the Psychology of the Angler's Fish. This last article deals for the most part with artificial baits and the author suggests that, just as a kitten will dash at any moving object at the end of a string, so a fish will seize any small object moving rapidly before its eyes. Support is lent to this view by reason of the fact that artificial bait, except when in motion, is practically useless as an attraction for fish. Other articles are the Protective Colouration of Plumage and Eggs, by Mr. Thomas Hepburn; British Bats: How to Tell Them, by Mr. H. E. Forrest; and the Feeding of Snakes in Captivity, by Mr. B. Ingram, L.R.C.P. & S. Edin. The articles on British Field Geology and Zoology are continued. It is much to be regretted that this excellent magazine does not appear more often than once a quarter.

NEWTON ABBOT HOSPITAL.—The annual meeting of the subscribers to the Newton Abbot (Devon) Hospital was held on Jan. 19th. The medical report stated that during the past year the in-patients numbered 270, the out-patients being 774, both figures being in excess of those for 1903. The financial statement showed that the income amounted to £1210, while the expenditure was £1088. Dr. E. Haydon, Dr. J. Culross, Dr. W. G. Scott, Dr. A. T. Nisbet, Mr. R. H. Grimbly, Mr. E. Hunt, and Mr. J. J. S. Scrase were re-elected members of the honorary medical staff.

THE LANCET.

LONDON: SATURDAY, JANUARY 28, 1905.

Apparent Death and Death Certification.

A REMARKABLE account of a case of apparent death was reported last week. From the facts stated in the daily papers it appears that a married woman named HOLDEN, aged 28 years, and living at Hapton, near Accrington, was believed to be dead. Her body, clad only in a nightdress and covered by a sheet, was laid out in an icy-cold room in the usual manner. Some six hours subsequently the undertaker whilst measuring the supposed corpse for a coffin observed a twitching movement of the eyelids. He had the presence of mind to resort to artificial respiration, with the result that "slowly and with trembling uncertainty an arm was raised, glassy eyes quivered in ghostly fashion, and a hand still deathly cold clutched at his own." The further history of the case is that vitality became more and more established until the woman could converse in feeble accents. There seems to be no shadow of doubt that Mrs. HOLDEN was believed to be dead, for funeral coaches were ordered, an insurance company was informed of the death, and the doctor's certificate was obtained. The medical man who had seen his patient on the previous day was not surprised to hear of her death. There are certain facts in the history of Mrs. HOLDEN'S life which tend strongly to explain her state of suspended animation. In the first place, she had been ill for a long time with general weakness and for several weeks she had been confined to bed. She had obviously assimilated but little food and had been subjected to the depressing influence of cold—conditions such as are found in hibernating animals during their winter sleep. There appears also to have been a predisposition to the cataleptic state, for twice previously, once as an infant and again as a girl of 15 years, she is said to have lain as if dead. Moreover, it was disclosed that she had been subject to "fits," a definite cause of exhaustion.

BROUARDEL in his work "Death and Sudden Death" gives many illustrations of simulated death, such as the trance-like condition of the Indian fakirs, the state of children apparently stillborn and that of people the subjects of hysteria with long-continued fasting, syncope or inhibition, hæmorrhage *ad deliquium*, submersion, exposure to extreme cold, drunkenness to the extent of being *dead drunk*, cerebral concussion, anæsthesial collapse, and acute diseases such as cholera. It is obvious that to the ordinary observer this condition of apparent death may on rare occasions be mistaken for the reality. It is even possible that the skilled practitioner may have difficulty in establishing the moment at which life has departed in cases where the transition has been extremely gradual. It is beyond the bounds of reasonable probability, however, that a medical man would fail to determine by careful, complete, and repeated observation whether a body were alive or dead. It has been said that the only infallible sign of death is decomposition and taken singly this is true. If all the collective indications of death prior to disintegration of the tissues are obtained we do not hesitate to affirm that the fear of a person being buried alive is practically groundless. We know of no thoroughly authenticated case in which a body after it has been pronounced dead by competent and honest examiners has "returned to life." Thus there is ample consolation for those who fear being buried alive and for those who possess the same feeling as regards friends and relatives. BROUARDEL remarks: "If a mistake has been made it is a popular blunder, not a medical one", and, again, "one fact is found to be almost constantly present—viz., in the immense majority of cases the persons died without having been seen during their illness by a physician, and were buried without a physician having had the opportunity of verifying their death." The real danger, then, lies not in the difficulty of establishing the fact of death but in the state of the law in this country and many parts of France which allows death certification, registration, and burial without demanding the verification of death by a qualified medical man. So long as the certifier is allowed to use the equivocal phrase "as I am informed" embodied in the official death certificates, so long will there remain the possibility of the simulacrum being mistaken for the reality. In the interests of science, humanity, and common honesty it is high time that the legislature should exact indisputable direct medical testimony that the person certified as dead no longer lives.

The Guildhall Conference on Feeding School Children.

SOME 250 delegates representing labour and other organisations, with a total membership of about 2,000,000, have met at the Guildhall and adopted a proposition in favour of the free maintenance of school children by the State. Only 13 delegates ventured to vote against the proclamation of the principle that this is a State and not a parochial question. It would seem that the full description given in these columns of the feeding of all the children attending the primary schools of Paris influenced many of the speakers.[1] Constant reference was made to the *cantines scolaires* and to the Paris schools. In such great questions every advantage should be taken of any practical experience that has been acquired abroad but it is not safe to venture upon too close an analogy between foreign and home institutions. Dr. MACNAMARA, M.P., made a good point when he said that as a municipal annual subvention of £45,000 sufficed to secure the feeding of all the children who attended school in Paris he thought that the same could be done in London, even if three times that amount were required, by adding only a halfpenny to the rates. But it does not follow, therefore, that the cost in England, and still less in London, should be thrown on the rates. Dr. MACNAMARA appears to forget that there are no rates in France and that in Paris there is no district or parochial taxation. Not only in regard to this new proposal for the feeding of school children but in most other efforts at sanitary improvement and poor relief the fear of increasing local rates is one of the main obstacles which arises in this country. It was at once pointed out that while the cost to the poverty-stricken ratepayers of West Ham or of Whitechapel would be enormous the "undesirable aliens" inhabiting Park Lane would have little or nothing to pay. This is not the case in Paris, for though, like London, the French capital is subdivided into boroughs—namely, the 20 arrondissements—taxation is, for the most part, uniform throughout, being in the main derived from the octroi or town dues. Such local taxes as are levied on the individual are devised especially to relieve the poor. Thus no tax is levied on any house or tenement if the rent does not exceed £20 per annum. Then the tax is progressive according to the value of the dwelling. Moreover, the revenue for the relief of the poor is to a considerable extent derived from a tax imposed on every occupied seat of the theatres and on every bet made at a racecourse. In such circumstances the throwing of the cost of a sanitary improvement or of some measure of poor relief on the municipal revenues in France has a very different practical bearing to that of charging the same upon the rates in England. It is an old-standing grievance that in London the poor rate is lowest in the wealthiest quarters and the meeting at the Guildhall strongly resented any proposal to accentuate the inequalities which were so obviously to the advantage of the wealthy.

---

[1] THE LANCET, Sept. 17th, 1904, p. 860.

On the fundamental point at issue the entire conference was unanimous: Sir JOHN GORST, M.P., who presided; Dr. MACNAMARA, who headed the minority of 13; Mr. JONATHAN HUTCHINSON, F.R.C.S.; and all the trade unionists, the Socialists, the Fabians, the philanthropists, and the educationists, one and all, were absolutely and most emphatically of opinion that somehow or other every child must be fed and no child allowed to study without first having sufficient food. It was pointed out that, on an average, the school rate amounted to 1*s.* 2*d.* in the £ and that a great deal of this money was wasted because the children were not physically fit to profit by the education offered to them. Mr. HUTCHINSON said that he did not believe that there was any general physical degeneration. The essentials of life were cheaper now than they have ever been and the wages were higher. The consumption per head of beef, rice, beer, and other such articles was much greater than formerly. This optimistic view, in our opinion, however, only applies to the epoch of modern industrialism and would not hold if compared with the condition of the workers in the Middle Ages. But Mr. HUTCHINSON might have added that the death-rate was lower than it had ever been before, including even the Middle Ages. These are all very strong arguments against the supposed general degeneration of the population. Nevertheless, such degeneration is only too obvious among certain classes of the community and in certain localities. Mr. HUTCHINSON urged that if there have been improvements there is still crying need for further progress. Therefore, and as a medical man, he pressed upon the conference that meals should be provided at schools for all children and this without any sort of distinction or inquiry so far as the children themselves were concerned. Perhaps there had been some exaggeration as to the number of children said to be starving but there could be no doubt that an enormous proportion of them were inappropriately fed. For instance, milk is obviously very essential for young children, yet a large section of the community cannot afford to buy milk. He thought that every child should be offered a bowl of hot milk and bread on arriving at school. Then he urged that the boys should be taught how to wait at table, the girls how to cook, and playmasters should be appointed to organise suitable games during the hours of recreation. All this could be managed better and cheaper on wholesale lines at school than at home. The entire community would profit when this was done for the children. The State had a duty to perform in this respect. Finally, Mr. HUTCHINSON said that parents bore an unequal share of public burdens and when the State helped it would be a means of enabling those who had no children to contribute to the raising of future citizens. This, by the way, is the principle on which workmen's benefit clubs are organised in South Wales.[2] As a practical means of bearing each other's burdens bachelors are made to subscribe as much for themselves alone as married men for their whole families.

Thus the delegates at the conference all agreed that the children must be fed and, so that the burden might be more evenly divided throughout the whole community, most of them were in favour of State instead of local maintenance. But this word maintenance means a good deal more than mere feeding. In Paris it means boots and pinafores and other articles of clothing for the very needy. It also means, and this is more important from the medical point of view, that at least the sickly children shall spend their holidays at the seaside or in the country. From the Montmartre district four batches of 186 children are sent annually for a few weeks to the magnificent historical mansion and park of Luzancy. From the neighbouring seventeenth arrondissement 137 children were, according to the last figures given, sent to the seaside at Fécamp and 381 to the country at Montlhéry, and altogether they spent 8500 days in the pure air. To facilitate such outings the municipality gives £8080 to the twenty Paris districts. So also at the Guildhall meeting it was felt that feeding did not cover all the requirements of the case, hence the word maintenance. But while everyone agreed that it would be indeed most admirable to supply these and many other things to the children of the nation opinions very promptly began to divide when the question of payment was raised. Nevertheless, even on this point everyone seemed to think that the cost, however large, would prove an economy in the long run. Not only would a more healthy and intelligent race produce more wealth but there would be fewer people to keep at the public expense in prisons, workhouses, and hospitals. Then also the question of thriftless drunken parents was raised. This was met by the argument that the only way to rid the community of its most worthless members was to remove their children and so to educate them that they should not grow up like their parents. This, again, would be an economy in the long run. It is scarcely within our province to discuss in detail what are the best methods of taxation for such a purpose or to consider the proportion of the cost that should, or could, be recovered from the parents. In Paris, in the poorer quarters, 70 per cent. of the children are fed gratuitously and the remainder pay only 1½*d.* for a meal of three courses. But we can at least insist on the obvious fact that the children are not responsible for the shortcomings of their parents; that if they are to grow into healthy and useful citizens they must be well fed, well clothed, and well housed. How these necessities are to be rendered available for all is a problem which will need more than one Guildhall conference to solve. But it is something to find that there is an awakening of the public conscience on the matter and that a strong desire is manifested on all sides that every child should have wholesome and sufficient food.

[2] Organisation of the Profession, THE LANCET, Feb. 14th, 1903, p. 479.

The Influence of Climate on the Incidence of Disease.

WE have recently published an interesting communication by Dr. WILLIAM GORDON on the influence which rainy winds exert on the prevalence of pulmonary tuberculosis.[1] With the discovery of the tubercle bacillus there was a natural tendency to ascribe to that organism a paramount rôle in the causation of the disease and to consider heredity and other supposed causal factors as of but secondary consequence. Subsequent research has demonstrated that this conclusion is a mistaken one, not only from the point of view of etiology but also of therapeutics. It is now generally recognised that although tuberculosis cannot arise without the presence of the pathogenic bacillus other agents must be present which are of equal importance. The exact nature of these agents is still in dispute. They are generally included under the convenient though rather vague term of "deficient resistance." Any cause which lowers the natural physiological perfection of an organ renders that organ more prone to the attacks of micro-organisms—and of such causes there are many. Dr. GORDON refers to some of the conditions which tend to influence the prevalence of pulmonary tuberculosis and he sets himself the task of proving three propositions: (1) that in many countries exposure to prevalent strong rainy winds is accompanied by increased mortality from pulmonary tuberculosis; (2) that in those health resorts which have been shown to be most favourable for the treatment of the disease prevalent strong rainy winds do not exist; and (3) that with the exception of the predisposition of certain races to pulmonary tuberculosis and of the effect of certain injurious occupations the influence of these winds on the prevalence of the malady is more powerful than that of any other factor.

Dr. GORDON has taken great pains to collect reports as to the prevailing winds in different parts of the world. He further states whether they are rainy or dry and then compares the distribution of pulmonary tuberculosis (as shown by the death-rate from the disease) with the occurrence of these winds. For the details of this investigation we must refer our readers to the original article. The information thus derived will be found interesting from many points of view. He certainly shows that the prevalence of strong rainy winds is remarkably associated with increased prevalence of pulmonary tuberculosis. For instance, in England the prevailing rainy winds are south-westerly, westerly, and north-westerly, whilst the region of maximum occurrence of the disease in the years 1871–80 stretched along the western side of the country from Cumberland to Cornwall. The western counties are thus the most exposed and have the highest death-rate from tuberculosis. On the other hand, Rutland, Worcester, Hereford, Stafford, and Shropshire, which are all sheltered, have the lowest death-rates. To take another instance, in Spain the heaviest rainfall is on the northern and north-western coasts, where the Atlantic gales are fully felt. The least rainfall and least wind are on its south-eastern coast at Malaga and Valentia. The death-rates from pulmonary tuberculosis in these two regions are as strikingly different as their wind and rain are. Dr. GORDON'S contention is in some measure supported by the experience gained at the sanatoriums where the "open-air" treatment is carried out. The patients seem to suffer but little from rain alone but when wind is added the greatest inconvenience is experienced and the customary exercise can only be undertaken behind "wind screens" or in walks naturally sheltered from the wind, for as SHAKESPEARE long ago pointed out, "Many there be *can brook the* weather that love not the wind." Dr. GORDON'S remarks in reference to the occurrence of wind and rain in the "most successful phthisis health resorts" are not so convincing. He admits that at present it would be scarcely justifiable to impugn the resorts which are subject to rainy winds but he proceeds to inquire as to whether "any admittedly very successful health resorts" are exposed to them. This phraseology is not altogether fortunate, for expert opinion is by no means uniform as to what may be considered the essential qualifications of a spot suitable for the treatment of tuberculous disease. Experience shows that many regions in this country are well adapted for the erection of sanatoriums, whilst some authorities maintain that a perfectly dry atmosphere is necessary. It is generally recognised, however, that shelter from strong and wet winds is necessary and Dr. GORDON maintains that freedom from such winds characterises the resorts to which he refers as being "very successful."

In the third part of his paper Dr. GORDON proceeds to consider the relative strength of other influences known, or supposed, to affect the occurrence of pulmonary tuberculosis. Amongst these he enumerates soil, altitude, temperature, rainfall, density of population, insanitation, occupation, race, and several others. The question of "heredity" is entirely omitted. This is certainly a large subject in itself but the observations would have been more complete had some allusion been made to it. The conclusions at which Dr. GORDON arrives are interesting. He considers that soil has a definite influence but not a marked one; that altitude has little effect, as has the rainfall. He sums up his opinion in the following words: "The influence of exposure to rainy wind therefore appears to have a greater effect in increasing the phthisis death-rate than any other influences except those of differences of race and of occupation—and difference of race must be extreme—and injurious occupation must be almost universal in a community to produce as great an effect as exposure to rainy wind." The result of Dr. GORDON'S inquiry is certainly interesting. The evidence which he has accumulated lends force to his contentions and he has marshalled his facts in a manner which goes far to establish conviction. If it cannot be said that he has entirely elucidated that mysterious factor "deficient resistance" he has certainly brought into strong relief climatic conditions which have great influence on the occurrence of pulmonary tuberculosis.

---

[1] THE LANCET, Jan. 7th (p. 10) and 14th (p. 77), 1905.

Our readers' attention may also be directed to an article by Dr. JAMES W. RUSSELL which appears in our present issue "On the Relation between Various Atmospheric Conditions and the Occurrence of Cerebral Hæmorrhage." He brings forward statistics to show that a high barometric pressure is a factor in deciding the onset of an attack of cerebral hæmorrhage. He maintains that there seems to be a slight tendency towards the occurrence of such attacks on days of high atmospheric pressure and also on days of rising pressure, the former probably exerting the greater influence. There seems also to be a marked tendency to the occurrence of hæmorrhage on days of low wind pressure and the combination of a low wind pressure with high barometric pressure is the condition under which the number of cases is highest. The question is an interesting one and merits further investigation.

The influence of climate on the incidence of disease is a complicated one and has received close attention from many observers, more particularly in relation to tropical disease. The two papers to which we have referred open up the subject in fresh directions and are of particular interest in dealing with diseases which are unfortunately of frequent occurrence in this country.

◆

Major Seaman's Address before the International Congress of Military and Naval Surgeons at St. Louis.

THE address of Major LOUIS L. SEAMAN, M.D., of the United States army, delivered before the International Congress of Military and Naval Surgeons at St. Louis in October last—a report of which is now before us—deals more especially with a subject—namely, the Japanese Military Medical Service—which possesses an unusual degree of interest at the present time. In order rightly to understand the address it is necessary to advert very briefly to the circumstances which gave rise to it.

Major SEAMAN, accompanied by his assistant Dr. TRAUTMAN of New York, arrived at Tokio in June, 1904, armed with all the necessary official credentials for acting as a medical attaché in the Russo-Japanese war. After some inevitable delay the much-coveted pass that was to take them to the front was obtained from the Japanese authorities. Just before leaving Manchuria Major SEAMAN was asked to contribute a paper at the meeting of the International Congress on the medical features of the war. The address in question is the result of that request. In complying with it MAJOR SEAMAN warns his audience that his paper is not to be regarded as a scientific digest of what had occurred but merely as a narrative of some of his personal experiences, together with a few conclusions drawn largely from observation in this and in other wars. Quite apart, however, from some points of scientific and surgical interest, to which we need not now more particularly allude, the chief value of the address consists in the fact that its author deals with his subject in such a graphic, bold, and vigorous way as to leave no room for doubt about the impressions which he derived from all that he saw and heard at the seat of war. The effect produced by his personal experience and observations in Japan and Manchuria led Major SEAMAN to form the very definite and optimistic views in regard to the excellence and efficiency of the Japanese medical and sanitary systems which find forcible expression in the published report of his address. And it is mainly to this aspect of the subject that we now briefly refer. As regards the organisation and practical working of the Russian hospital system in this war the information at our command is relatively scanty and as regards the number of Russian sick and wounded with the results attained under it our information is not only incomplete but conflicting and untrustworthy. In the case of Japan, although it is too early to obtain statistical proof of the assumption that a relatively large reduction in the percentage of mortality from wounds and disease has taken place, nevertheless careful observation and the records of Japanese hospitals seem to point strongly in this direction. Major SEAMAN in any case confidently predicts that this will prove to be the case and gives several incidents as grounds for his faith in this respect. We may quote, for example, the following: "Up to August 1st 9862 cases had been received at the reserve hospital at Hiroshima, of whom 6636 were wounded. Of the entire number up to that time only 34 had died." Again, "To July 20th the hospital ship *Hakuai Maru* alone brought 2406 casualties from the front without losing a single case in transit. Up to July 1st 1105 wounded—a large proportion of whom were stretcher cases—were received at the hospitals at Tokio; none died and all but one presented favourable prognosis." Contributing factors to this happy result have been the application of the principle of non-interference with wounds and thorough antiseptic methods of treatment. But it is in the case of the sacrifice of lives to preventable disease that the Japanese success has been most marked. The loss from this class of disease in the first six months of the campaign will, Major SEAMAN confidently believes, prove to be but a fraction of 1 per cent. "History," he remarks, "will never again furnish a more convincing demonstration of the benefit of a medical, sanitary, and commissary department, thoroughly organised, equipped, and *empowered* to overcome the silent foe." A large portion of the address is taken up with a comparison between these remarkable results and those of other wars; our own campaign in South Africa, the Spanish-American war, and the French losses in Madagascar may be given as examples. It has nevertheless to be borne in mind that as regards some of their sanitary methods and procedures the Japanese have still something to learn, if we may judge from what a special correspondent has to say on the subject in his "Medical Notes from the Far East," published in another column of our present number.

We have only touched the fringe of Major SEAMAN'S address but we have said enough, we think, to show that the Japanese have exhibited a preparedness, a capacity for organisation, and a mastery and adjustment of details to the practical purposes of war in their sanitary and hospital arrangements which account for the results which Major SEAMAN records with so much appreciation. Like all stories worth the telling the moral lies on the surface and the war in the Far East should be regarded as an object lesson for all those who have to deal with the sanitary and medical aspects and requirements of modern warfare.

Annotations.

"Ne quid nimis."

THE LATE SIR JOHN SIMON'S SURGICAL WRITINGS.

AMONG the MSS. of the late Sir John Simon recently purchased for the library of the Royal College of Surgeons of England are some notes dictated by, or in the handwriting of, the great sanitary reformer which deserve attention as showing the attitude of Simon towards his own publications. Taken together they form a kind of medical and surgical last will and testament, having been written, to judge by internal evidence, in the middle "nineties" of the last century at a time when Sir John Simon was already a very old man. Inserted in the MS. of a proposed reprint of his well-known paper on the Comparative Anatomy of the Thyroid Gland, published in the "Philosophical Transactions" so long ago as 1844, is a note in which Sir John Simon confesses that at the time of publication he was unacquainted with Johannes Muller's work on the myxinoids (1834–39). "The writer [Simon], though now at a distance of 50 years from the times referred to, still regrets that in respect of part of his inquiry he was unacquainted with Professor Müller's classical work, but on consideration he has not deemed this a reason for suppressing the present paper. He, of course, assumes that it will not now be read without the check (where applicable) of Professor Müller's treatise; but he further believes that his own essential point, which is to suggest the connexion of the thyroid gland with the brain, had not before this publication been argued and is still deserving of skilled attention." In a note prefixed to a projected reprint of his paper on Sub-acute Inflammation of the Kidney, originally printed in the Transactions of the Royal Medical and Chirurgical Society in 1847, Simon, *circa* 1895, candidly admits "his present belief that the opinions he expressed in it [the paper] with regard to cyst-formation in the kidney were probably erroneous; that probably the early forms which he believed he saw of cyst-formation were in truth but the washed-out remnants of tubules. In other respects he believes the paper to be sound and that some of the doctrines expressed in it may perhaps even still be serviceable." Referring to his now classical article on Inflammation in Holmes's "System of Surgery" Simon pens the following semi-biographical note which is interesting as being the composition of a great thinker at a time of life when most old authors have long ceased to write anything. "At the time when the writer began his official engagement under the Privy Council he had a fair margin of leisure for collateral work in his profession and during the nine months from October, 1859, he used this opportunity to contribute the opening article *Inflammation* to Mr. Timothy Holmes's 'System of Surgery,' then in first edition; but some nine years later when a second edition of the work was to be issued, and this at a moment when Professor Cohnheim's recent contribution to the subject demanded careful consideration, he did not feel himself able to undertake more than a portion of the duty; and in such editions as have been issued since that time he has reluctantly been quite unable to participate. Whether his original article may perhaps still deserve to be read as a whole by the advanced student who can put aside its superseded portions is a matter on which the writer will not pretend to judge; merely observing that the article in its main argument seems to him to be still valid." As further appears from the same note Simon proposed to reprint those parts of the article in Holmes's "System" which refer to "*the production of heat in inflamed parts*" and "contagia in the inflammatory process." The articles on the thyroid and the kidney he proposed to reprint *in extenso*. These short notes by Simon afford a curious commentary on the current opinion that works on medicine and surgery become superannuated and valueless in a decade at the most.

THE OBSTETRIC DUTIES OF THE ARMY SURGEON IN AMERICA.

THE soft answer that turneth away wrath is, as a rule, by no means characteristic of controversy, especially in the scientific branches thereof. The fields of theological and of biological argument are especially prone to bring forth a crop of personal recriminations which is unworthy both of the dignity of the subjects discussed and of the intellects of the protagonists. A specimen of courteous argument now lies before us which comes from that great country of our kinsmen, the United States of America. Dr. Joseph Jeffrey wrote a letter to the editor of *American Medicine* which appeared in the issue of Feb. 8th, 1902, containing the innuendo that the opinions of Major Charles E. Woodruff, "an army surgeon of several campaigns," on obstetrics and such allied topics as maternal impressions were about as valuable as his (Dr. Jeffrey's) opinions on camp sanitation. To this Major Woodruff, who has answered in no undignified haste, replies in a long letter appearing on Dec. 24th, 1904, and written in a vein of Gilbertian pleasantry. Army surgeons are really obstetricians, he says; "they are supposed to be official experts in the specialty of military medicine, including all the branches of camp and barrack sanitation, relations to health of clothing, climate and food, modifications of civil surgery found necessary in the same classes of cases far from modern operating rooms, whether found on the battlefield, lines of communication, or in temporary sheds in dirty surroundings, where a modern surgeon would not dream of operating, diseases peculiar to troops, anthropology as related to the selection of recruits, and a host of other sub-branches about which a civil physician never bothers. But *legally army surgeons are specialists in only one thing*—obstetrics." By a Bill passed in Congress it is the duty of officers of the medical department to give gratuitous professional services to the families of officers and soldiers where practicable and it is the "right and duty" of the post commander to inquire "why it was the surgeon spent so much time with Lieutenant and Mrs. X instead of being at the hospital; and the surgeon will have to explain the details of the obstetric case if required." Formerly the relations between practitioner and patient were privileged as in civil life. Now it seems "army ladies are the only ones entitled to have the details of their obstetric trials recorded in the national archives." Again, the Secretary of War can place medical officers on any duty as he thinks best but no duty is explicitly stated by law except obstetrics. Whatever duty the officer may be doing he can be wired for by Mrs. X for obstetrics, if he wants vacation leave he must put it off for obstetrics, his first duty in all cases is obstetrics. "Is it any wonder, then," Major Woodruff asks, "that after watching for 15 years the official *début* of military babies our minds, in accordance with the law, should run to maternal impressions?" (The subject of the controversy.) Unless he learns all about this matter the writer points out that he is not competent to fulfil the law, however well he may be able to perform the duties connected with his chosen calling. The letter, which would occupy about three columns of THE LANCET, effectively answers the purpose for which it was written in a spirit of perfect good humour. If all unkind innuendoes made in the heat of controversy were replied to in a similar manner we should hope for the dawn of the millennium in the very near future. But we fear that the time is not yet—at any rate not in this country, however it may be across the Atlantic.

THE DEFINITION OF WHISKY IN OLDEN TIMES.

WITH reference to the recent discussions on the purity of malt whisky and of the adulteration of whisky with patent-still spirit it is of interest to learn the precautions which were taken by the Scottish Parliaments centuries ago to protect the purity of Scotch whisky. A correspondent who has been investigating the subject in the British Museum sends us the following excerpts taken from old documents on the subject. In seeking for a definition of whisky or brandy due regard, it seems to us, is bound to be paid to the original meaning of these words.

"Accounts of the Lord High Treasurer of Scotland," edited by Thomas Dickson, 1877.—Vol. I., p. c. c. XIII.

Whisky or Aqua Vitæ, date 1494-5.

The Exchequer Rolls show a delivery to Friar John Cor of eight bolls of malt to make aqua vitæ. That it was not largely manufactured nor in general use at the time is shown from the comparative rareness of its occurrence, as well as from the manner in which, on the occasion referred to, it was furnished to the King. It was probably reckoned rather among drugs, than among articles of ordinary consumption.

There is a footnote to the above as follows :—

Fratri Johanni Cor, per preceptum compotorum Rotularis, ut asserit de mandato Domini regis ad faciendum aquæ (*sic*) vite VIII. boll brassij.

The next notice of the use of aqua vitæ is to be found in the index to the Acts of Parliament of Scotland in the British Museum, where we note that in 1579 the following law was passed :—

No one to make or sell aqua vitæ from 1st Dec. to 1st Oct. next except earls, lords, barons, and gentlemen for their own use.—C. 56, III. 174.

Later the value of the trade seems to have been realised, for in 1655 we see that :—

The importation of aqua vitæ or strong waters was prohibited.—VI. II. 828a.

In 1655 the town council of Glasgow issued regulations for persons who should "brew, sell and tap aqua vitæ," and further in the same year : —

An excise of 2*d*. per gallon English, or quart Scots, imposed on aqua vitæ or strong waters distilled in Scotland; of 4*d*. per gallon English or quart Scots on spirits *made of wine imported; of* 1*s*. per gallon English or quart Scots on spirits sold instead of aqua vitæ or strong waters.—VI. II. 828a, 828b.

Already the Scotch had seen the danger of whisky being adulterated and at once took steps in the shape of a heavy duty to guard against such adulteration. In 1663 they went further still, for they then passed a law to the effect :—

Importation of foreign aqua vitæ prohibited.—C. 13, VII. 458.

In 1672 we find :—

Ratification to Edinburgh of an import on foreign aqua vitæ, strong waters and other foreign spirits distilled.

These laws show that the Scotch, more than 200 years ago, were alive to the danger of the adulteration of whisky with foreign spirit and took care by their laws to protect their pure malt product. And that whisky was a pure malt product is shown by the next two enactments, as well as by the first paragraph of this article, in which it is stated that eight bolls of malt were supplied to Friar John Cor. We find then in 1695 :—

An excise imposed of 3*s*. per pint on aqua vitæ and strong waters, not made of *malt* brewed and sold within the kingdom; of 6*s*. per pint on aqua vitæ, brandy, and strong waters (probably foreign); and 13*s*. per barrel on foreign beer.—IX. 451a.

Again in 1705 :—

A tack of the excise on aqua vitae made of *malt*, set in 1698 for five years to Sir William Menzies for £40,000 per annum to be paid quarterly.—C. 2. X. 31.

A "tack" in Scotland is a lease. So it seems clear from these old laws that whisky was originally a pure all malt spirit and that adulteration by means of foreign spirits was either entirely prohibited or had to be paid for at a prohibitive rate. It is a pity that the Government of the present day cannot do for us what an enlightened Scotch Government did for its people more than 200 years ago.

MEDICAL ARTICLES IN LAY JOURNALS: THE PREVALENCE OF HOOKWORM DISEASE IN PORTO RICO.

A CORRESPONDENT writes :—

Several of the principal lay papers of the United States have recently come to an appreciation of the fact that their readers take great interest in medical affairs and particularly in matters concerning public health. In order to supply news of this character in an accurate manner some of the journals have initiated the system of procuring as members of their staff competent medical men whose duty it is to supply authentic and reliable medical literature and to supervise papers which come within their especial sphere. With this object in view the *New York Herald* has recently sent to Cuba and Porto Rico the following three well-known physicians: Dr. Wolfred Nelson, F.R.G.S., a graduate of McGill University; Dr. P. Jenkins, formerly health officer and health commissioner of New York City; and Major Louis L. Seaman, U.S.A. Drs. Nelson and Jenkins were despatched to Cuba in order to investigate the reported outbreak of yellow fever there, while Major Seaman went to Porto Rico. Letters have been received and published in the *Herald* from all three of these doctors, that from Major Seaman being especially interesting. Dr. Seaman has found that the hookworm disease prevails to a remarkable extent among the inhabitants of Porto Rico, rendering the majority of them unfit for active work. The investigator states that the unsanitary conditions of the island, contributing largely to the production of the disease, are the result not of intentional neglect, but of environment and of inherited habit, for which the living generation cannot be held altogether responsible. The writer gives it as his opinion that the uncinariæ gain entrance into the system through the naked feet of the farm labourers whence they work their way into the intestines, become encysted, and develop into full-fledged blood-suckers [illegible] ine the vitality of their unconscious host. [illegible] are means to rid the soil of the nematode [illegible] generally of effective sanitary arrangements, and the education of the people as to the need of thorough personal hygiene. Major Seaman, moreover, makes the suggestion that free clogs should be provided for the labourers in agricultural districts of Porto Rico in order to protect their feet. The example set by the *Herald* in sending out a commission to Cuba and Porto Rico in the interests of public health is one wholly in keeping with the progressive character of that journal, and the trend of many of the principal newspapers here of supplying their readers with authentic medical news and with articles bearing on medical subjects properly written is a distinct advance in modern journalism.

The *New York Herald* has evidently gone to work in the right way to obtain accurate information on certain medical questions of national (or rather international) importance and by publishing in its columns suitable articles on such topics it can, and no doubt will, render the community a great service. It will be observed that the subjects dealt with are essentially matters of public hygiene, the remedial treatment of which can hardly be effective except under two conditions—namely, when constituted authorities take the initiative and when the general public loyally support the efforts of the administration. Public opinion, however, requires to be formed and guided—an educational process which in America naturally comes within the province of the journalist. So long as the medical articles in the ordinary newspapers are confined to general questions of sanitation and the prevention of disease much good may be done, but in the absence of proper editorial supervision the practice is not unlikely to lead to a variety of abuses. Newspapers of the standing of the *New York Herald* are under no temptation to increase their circulation by meretricious aids but there are countless journals of a lower rank which would find discussions on the prevention of disease insufficiently attractive and would seek to draw attention to themselves by dissertations on any medical topic which might be exciting the public imagination at the time, whether the pathology of cancer, or the surgery of the brain, or "bloodless surgery," or hypnotism, or hydrophobia, or the treatment of special diseased conditions, and so on, *ad infinitum*.

COLLAPSE DURING EXAMINATION OF A POST-PHARYNGEAL ABSCESS: RE-ESTABLISHMENT AND MAINTENANCE OF THE CIRCULATION FOR FOUR HOURS BY MEANS OF MASSAGE OF THE HEART.

IN the *Boston Medical and Surgical Journal* of Jan. 5th Dr. David Cheever has recorded the following remarkable case in which the circulation was re-established and maintained for four hours by means of massage of the heart. A girl, aged three years, was taken to hospital complaining of sore throat and dysphagia. There was a history of a fortnight's illness, with feverishness and anorexia. The child became progressively worse and unable to eat or to talk. During the last few days respiration became laboured. On examination she was pale and ill nourished, with a pulse of 140, respirations 46, and slight cyanosis of the finger tips and the lips. The respiration was shallow and a few moist râles were heard at the bases of the lungs. There was a diffuse fulness on the right side of the neck which was not tender. A swelling obstructed the oro-pharynx but the struggles of the child made complete examination impossible. An operation was undertaken. As it was impossible to reason with, or to gain the confidence of, the child the necessary manipulations were carried out by force but as gently as possible. The arms were confined by a blanket and she was held in the nurse's lap. No anæsthetic was given and she struggled ceaselessly. The introduction of the gag caused such choking and cyanosis that it had to be withdrawn—with immediate relief. At a favourable moment it was again placed in position and the finger and knife were introduced but a point of fluctuation could not be felt. Breathing suddenly ceased and the child was laid on the table and artificial respiration was begun. The pulse could not be felt nor could the heart sounds be heard with the stethoscope. The face and the mucous membranes were moderately cyanotic, the pupils were dilated and immobile, and the cornea was insensitive. The time was 6.20 P.M. With the child in the Rose-Trendelenburg position the abscess was opened and evacuated. As auscultation showed that a satisfactory amount of air was not entering the lungs a rubber catheter was introduced through the mouth into the trachea and the expansion of the chest by manipulation was supplemented by insufflation. No improvement ensued and the cyanosis was followed by extreme pallor and there were no signs of action of the heart. Cardiac massage was begun by rhythmical pressure at the rate of 60 to the minute over the third, fourth, and fifth left costal cartilages. This process with the artificial respiration was continued for four and a half hours until further efforts were evidently useless. As rapidly as possible brandy and strychnine were injected directly into the heart, the legs were bandaged firmly from the toes to the groins, the abdomen was manually compressed, and heat and blankets were applied. Directly following the pressure over the heart the colour returned to the lips and the face and the capillary circulation could be demonstrated by the blanching and the return of colour after pressure on the cheeks, the tongue, the lips, and the nails. No heart sounds were heard with the stethoscope at any time but feeble pulsations were detected in the radial and the femoral arteries, always immediately after the pressure on the heart; they were never felt when the pressure was interrupted for a moment. The pupils remained dilated and immobile. Oxygen under considerable pressure was forced into the lungs through the catheter but the colour of the mucous membranes at once became worse, therefore insufflation was again begun. At 8.30 a pint of saline solution was infused into the median cephalic vein with transitory improvement of the colour and the pulse. There were sluggish oozing from the subcutaneous tissue and marked hæmorrhage from the vein. The blood was slightly darker than normal. Ten minims of solution of adrenalin were injected into the pectoral muscle and repeated without noticeable effect. At nine o'clock the tube was accidentally withdrawn from the trachea. Its re-insertion was difficult in consequence of beginning rigidity of the jaw. Tracheotomy was therefore performed and insufflation was continued. The wound bled less than the previous one. The colour failed steadily and the skin became mottled, although the capillary circulation could still be demonstrated in the lips. Finally it was determined to inject stimulants into the spinal canal but in turning the body over it was found that rigor mortis was well established in the legs. Further attempts at resuscitation were therefore abandoned four and a half hours after they were begun. Death evidently was due to cardiac collapse from the shock of the manipulations performed in attempting to operate on an extremely exhausted patient. In endeavouring to maintain the circulation artificially Crile and others have shown that not only must the heart be kept beating but the blood pressure must be insured by increasing the peripheral resistance. Crile does this by injecting adrenalin which causes the vessels to contract and by the use of his inflated rubber suit which offers a resistance that can be regulated. In the above case resistance was produced by bandaging the limbs firmly and compressing the abdomen. Keen has recently collected 27 cases in which massage of the heart was used for resuscitation, of which three were successful, and Cohen has reported a successful case. In some cases the pericardium has been opened and the heart rhythmically compressed but the circulation has never been more than temporarily restored. In a case described at the Society of Anæsthetists by Dr. E. A. Starling[1] the pulse and the respiration stopped together during the operation for removal of the vermiform appendix. The surgeon, Mr. W. Arbuthnot Lane, introduced his hand through the abdominal incision, felt the motionless heart through the diaphragm, gave it a squeeze or two and felt it commence to beat. After artificial respiration the patient recovered and the operation was completed without more anæsthetic. Good convalescence followed. In an annotation published soon afterwards[2] we discussed the whole subject of resuscitation by compression of the heart. Dr. Cheever calls attention to the fact that his case differs from most of the others recorded in that automatic cardiac pulsation was not re-established. He thinks that the blood was pumped through the vascular system by the mechanical pressure on the heart, which seems to us very doubtful.

THE SALE OF PATENT MEDICINES IN NEW ZEALAND

A RECENT issue of the *New Zealand Gazette* contained regulations issued under section 101 of the Public Health Act, 1900, with effect from June 30th, 1905, notifying that: "All patent medicines imported or sold or offered for sale in the colony shall be required to have the contents with their exact proportions legibly set out in English upon a label affixed on the bottle, box, or container. In addition to such information, where such medicines contain one or more of the poisons scheduled under 'the Sale of Poisons Act, 1871,' and its amendments, the words 'This contains poison' must be marked in a clear medium-sized block type upon the label." The regulations provide that any person who commits a breach of, or fails to comply with, any of the foregoing regulations shall be liable, on conviction, to a penalty not exceeding £50. For the purposes of the regulations the term "patent medicines" is declared to include, *inter alia*, certain articles which are specified by their usual titles. Among them we observe a certain number of food preparations sold under distinctive names by well-known firms of high reputation, together with the "special extra strong female pills," "diabetes cures," "witches' oils," and other nostrums of the quack. From this it is clear that the administrators of the Public Health Act of New Zealand use the term "patent medicine" in a general and popular sense and not in its strict meaning of a medicinal compound protected by letters patent. They will, if they vigorously carry out their regulations, protect the public in an efficient manner without causing inconvenience or injury to honest traders who are perfectly satisfied that the nature of what they sell should be known and who have no misgivings lest their goods should fail to contain the constituents of which they should be compounded. The vendors of much advertised "remedies," on the other hand, will have to make public the fact that their bottles and pill-boxes have nothing in them that can possibly account for the "cures" which they profess to have effected, and to these the legal provisions quoted should prove a serious stumbling-block. We note a good many familiar quack names among the titles scheduled as well as some which are new to us. If a similar measure were to be put into force in England the list would be a longer one and a large proportion of the advertisers in our newspapers and popular magazines would find themselves compelled to make statements which, if true, would condemn them as impostors and if untrue would render them liable to be fined.

THE ADULTERATION OF BRANDY.

IN two cases heard at Portsmouth police court on Jan. 17th, in which the defendants were alleged to have sold adulterated brandy, the bench failed to convict because in his evidence the public analyst admitted very properly that it was not possible to detect the difference between highly rectified grain spirit and highly rectified grape spirit by analysis. The words of the analyst's certificate were that the brandy contained 37 per cent. of spirit not derived from the grape. The fact is that "a spirit distilled or derived from the grape," though a principal definition and description, is not complete and this was well brought out in the judgment given by Mr. Fordham in the Islington case, the certificate of analysis in which contained precisely the same words as those used by the public analyst of Portsmouth. "I do not think," said this magistrate, "that after a spirit obtained by the distillation of wine has been so highly rectified as to have lost the properties peculiar to spirit so obtained, it is still spirit obtained by the distillation of wine so as to fulfil the definition of brandy." That is the crux of the whole matter. Silent or neutral spirit having its origin in the grape has no more of the qualities of brandy than has a spirit distilled from any other material. Otherwise the significance of the terms whisky, brandy, and rum is lost and they may as well be given up as meaningless. It would be well if public analysts could adopt the phraseology of the Government analysts when dealing with the results of the analysis of spirits which, at least in one instance, we know to be as follows: "From a consideration of the results of our analysis we are of opinion that it [brandy] consists of a mixture of pot-still grape spirit and neutral or patent still spirit. We estimate the proportion of the neutral spirit present at not less than 75 per cent." As we hold that brandy is only correctly defined as a pot-still grape spirit there would then be no escape on such a technical point as was raised in the case alluded to. We commend these facts to the Portsmouth bench.

THE DIRECTOR-GENERAL OF THE INDIAN MEDICAL SERVICE.

THE appointment of Lieutenant-Colonel G. Bomford, I.M.S., C.I.E., to the post of Director-General of the Indian Medical Service has been announced. He is M.D. Lond., was educated at King's College Hospital, London, and in addition to being a man of high professional attainments has shown considerable administrative capacity in the various important posts which he has filled; consequently he should prove a very fitting and acceptable head of the distinguished medical service to which he belongs. He is principal of the Medical College, Calcutta, and *ex-officio* first physician to the Medical College Hospital. For his services with the Perak Expedition in 1875-76 he was awarded the medal for that expedition with clasp.

THE MANAGEMENT OF THE DELIRIOUS PATIENT.

THE correct management of a patient whose illness culminates in acute mental delirium occasionally causes great anxiety to the medical adviser, more especially when the necessity arises in a public institution. Ten years ago Dr. Danford Thomas held an inquest upon a man who, having developed delirium (during septicæmia) in the London Temperance Hospital, had been summarily removed therefrom to the insane ward of the local parochial infirmary. The hospital authorities considered it inexpedient that he should remain in a general hospital to the annoyance of the other patients. The justice who visited him was unable to certify that his delirium was lunacy; he died ten days later. Last week the same coroner held an inquest at the Paddington Green court upon a case which illustrated a converse difficulty. A man suffering from acute bronchitis was admitted to St. Mary's Hospital; after four days' treatment he discharged himself while still very ill, obstinately refusing to give any reason for his conduct. Three hours later he entered a police-station and made ridiculous charges and complaints as to his alleged maltreatment in the hospital. The police, perceiving his delusions, conducted him to the Paddington Infirmary as an indigent person of unsound mind and there he remained without protest until his death from pneumonia and exhaustion. A magistrate who visited him the day after his reception not only was unable to certify insanity but forcibly commented on the action of the hospital authorities in allowing him to leave in the way and the manner described. These cases may be taken as types: in the former instance the resident medical officers considered their patient too delirious to be retained; in the latter they did not consider their patient sufficiently *non compos mentis* to be restrained, in fact, they feared that any duress on their part, medically justifiable perhaps, might result in actions at law for assault and for false imprisonment against themselves. The law does not recognise delirium as coming within the provisions of the Lunacy Acts, it matters not whether the mental derangement is part of an attack of acute alcoholism, acute apical pneumonia, enteric fever, or septicæmia, indeed it would be impolitic in medical practice to stigmatise as insane those who exhibit what is euphemistically called "brain fever" as a concomitant incident of their physical disease. The certification of these patients as having been even temporarily insane would lead to lasting resentment against the medical man who rashly advised it—a piece of worldly wisdom which it is well to remember in cases of puerperal delirium. Dr. Danford Thomas pointed out that if such cases were regarded as insane they might be treated legally as pauper lunatics and this would allow their speedy removal to the parochial infirmary. In private practice the difficulty of management is not so great, for the near relatives of the patient will at once agree to any precautionary measures which can be confidently recommended. In a public hospital, however, considerable circumspection may be needed when patients become obstreperous. Thus if a patient suffering from pneumonia attempts in his delirium to discharge himself through the window he would, of course, be restrained, but what if at an incipient stage of his madness, he insists on discharging himself through the door? In both cases the consequences may be equally, if not as quickly, fatal. When a man suffering from an acute disease submits to skilled professional treatment, is he not presumed to recognise the appointed medical authorities as placed over him *in loco parentis* and does he not tacitly submit to any reasonable line of treatment that they may adopt for his benefit? If this is the true relation it would justify the coercive duress necessary to prevent a patient from running headlong to wilful death, that is, unless and until a responsible person arrives who is able to appreciate the critical situation. No general hospital should be without an isolation room ready for the reception of noisy patients, and further, where a patient threatens to work harm upon himself the responsibility for his safety should be at once shared by demanding the presence of the police who will then be officially associated in the solution of a practical medico-legal problem.

THE WORKMEN'S COMPENSATION ACT AND SURGICAL OPERATIONS.

AT the Southwark county court an application made under the Workmen's Compensation Act to discontinue weekly payments made to an injured workman led recently to the discussion of a point which arises from time to time in these cases and will continue justly to form a subject for comment, although the law on the subject appears to be settled. The employers contended that the man had recovered from his injury and in the presence of conflicting medical testimony a medical referee appointed under the Act was called upon to report. This he did to the effect that the man was unable to perform his accustomed work owing to the presence of conditions which had been caused by the injury but which might be removed by surgical operation. The judge pointed out that he was unable to order a surgical operation, although the employers might persuade the workman to submit to one, and in the circumstances the application to discontinue the award was dismissed with costs. This decision although in accordance with previous ones does not prevent such occurrences from inflicting in some instances a considerable amount of injustice upon the employer or upon the company in which he insures his risks. Surgical science is capable of determining beforehand the varying probability of success of a large number of the operations called for when workmen are hurt in the course of their employment. No one would wish the injured person to be compelled to submit to surgical interference the result of which was clearly doubtful and the failure of which would, or might, leave him in a worse plight than before. At the same time no one can consider it just that a man should receive a pension and live in idleness when a reasonable man, independent of any pecuniary reward for his incapacity would certainly submit himself to a surgeon and by his aid regain the capacity for earning a living. In cases where jurors have to award damages according to their opinion of the extent of the injuries sustained the difficulty does not arise to the same extent, for the case can be presented to the jury so that they can estimate the degree in which the defendants should be held responsible. The damages under the Workmen's Compensation Act are simply measured by the duration and the degree of the incapacity to do work and other cases besides that alluded to have proved that the workman is fully aware of the advantages which the law has afforded him.

MULTIPLE GESTATION.

Dr. A. Pinard has contributed an article on gestation to the first part of the seventh volume of Charles Richet's fine "Dictionnaire de Physiologie," published in January this year. The last section of this article is devoted to multiple gestation and contains some interesting facts collected from a vast number of observations. In the first place, in regard to the circumstances that favour multiple pregnancies they include race, heredity, multiparity, age, and development of the ovaries. The influence of race is undoubted. It was demonstrated by Bertillon in an article which appeared in the "Dictionnaire Encyclopédique," and Tchouriloff in supporting the researches of Bertillon has pointed out that amongst racial characters height is of great importance and has expressed this in the aphorism, "height and gemellity decrease together." Heredity has a powerful influence on multiple gestation and there is strong evidence derived from careful observations that paternal influence is exerted, though no explanation of the fact has been advanced. In regard to age, the statistics of Lebel show that the largest number of multiple gestations occurs between the ages of 21 and 28 years; those of Dr. Pinard are in accordance with this but those of Puech give the ages between 25 and 35 years as most favourable for twin pregnancies. The observations of the last-named writer seem to show that one circumstance is not to be overlooked, the superior development of the ovaries which manifests itself in the production of two or more perfect ova capable of being simultaneously impregnated. Dr. Pinard has collected a considerable number of cases of superfecundation or, as he properly terms it, successive fecundation, such, for example, as the following recorded by Caillier, a veterinary surgeon at Mouhon. A mare was covered by a stallion and an ass in the space of half an hour. This mare gave birth in due time to a foal and within an hour afterwards to a mule. Cases of multiple gestation have been recorded in the human female. Thus Dr. Brittain communicated to the Edinburgh Obstetrical Society the case of a woman who at the age of 47 years had given birth to 25 infants in 14 accouchements. William Wood attended a woman in October, 1857, who gave birth to one boy and two girls and in the following October, 11 months and 22 days later, had twins. The wife of a Parisian shopkeeper named Brunet had, according to Sue, 21 infants in seven consecutive years. This man seduced a young servant who at the end of nine months presented him with triplets. These numbers are, however, far exceeded by the historical case of a peasant named Kinlow who in 1753 was presented to the Empress Catherine. He had been twice married. He had 57 children by his first wife—four times four infants, seven times three, and ten times two at a birth. By his second wife he had triplets once and twins six times. The French authorities have drawn their conclusions in regard to the frequency of multiple births in women from large numbers of recorded cases. Thus Dubois in 484,350 accouchements in Germany, England, and France found 6248 cases of twins, 78 of triplets, and four of four at a birth, or putting it in another form there was one case of twins in 78 deliveries, one case of triplets in every 6209 deliveries, and one case of four at a birth in 121,082 deliveries. Veit, basing his statement on the immense number of 3,360,557 deliveries, found that twins occurred in 149,934 cases, triplets in 1689 cases, and quadruplets in 36 cases, giving the proportion of one twin delivery to 89 single births, one triplet in 7910 births, and one quadruplet in 371,126 births. Dr. Pinard observes that the frequency of multiple pregnancies varies greatly in different countries. In France twins are delivered in the proportion of 1 to 92 single births, in Germany 1 to 84 cases, and in Great Britain 1 to 63 cases of single births. Bertillon expresses the proportion in which twin births occur in a different way. He finds that in 1000 confinements twins occurred 9·9 times in France, in Belgium 9·7, in Italy 11·4, in Austria 11·9, in Norway 12·5, in Prussia 12·5, in Holland 13·1, in Denmark 14·20, and in Sweden 14·50. Dr. Pinard observes that Bertillon's statistics in regard to Belgium are not in accord with Constant Leroy's experience who found 650 cases of twins in 39,508 single births. Finally, Dr. Pinard adduces the observations of Bertillon showing that in certain departments of France women bring forth twins more frequently than in others. Thus in Gironde, Haute-Garonne, Corrèze, Charente, Ain, Ardèche, Lozère, Gers, Cantal, Puy-de-Dôme, and Dordogne the proportion of twins in 1000 cases of pregnancy varied from 6·77 to 7·95, whilst in Finistère, Jura, Morbihan, Nord, Mayenne, Cher, Vaucluse, Vosges, Vendée, Moselle, Savoie, and Haute Savoie it varied from 11·36 to 12·90.

TYPES OF ALCOHOLIC INSANITY.

AN important discussion on the above subject was held at the Boston Society of Psychiatry and Neurology, an account of which is published in the *Journal of Nervous and Mental Disease* for December, 1904. Dr. H. W. Mitchell of Boston introduced the discussion in a paper based on the study of 148 patients (excluding cases of true dipsomania which exhibited no insane symptoms) at the Danvers Hospital for the Insane, or 13 per cent. of the male patients admitted. The cases were grouped as follows: delirium tremens, acute and subacute alcoholic hallucination, delusional alcoholic insanity, and alcoholic dementia. Two were cases of Korsakoff's psychosis polyneuritica of alcoholic origin. He found that among cases of delirium tremens "nearly all recovered without development of the graver forms of alcoholic insanity." The prognosis in cases of acute alcoholic hallucination was good for the attack but relapses due to renewal of drinking habits were common. These cases were characterised by vivid auditory and visual hallucinations, the former predominating, with little disturbance of consciousness and with transitory delusions probably based upon the hallucinations. In the case of subacute alcoholism there were auditory, visual, olfactory, and tactile hallucinations, with more prolonged persistence of delusions. Periodic relapses were seen in these cases during their stay in hospital, the intervals between the attacks being periods of practically normal mental condition. Permanent mental deterioration and dementia were the ultimate goal of this class of cases. Alcoholic delusional insanity was the term used for cases showing a development of delusions somewhat resembling paranoia. In many cases the delusions are elaborated from hallucinations. "Ideas of marital infidelity, poisoning, and persecution were most common in this class of cases." A tendency to incurable chronicity was observed in many and only a small proportion of cases recovered. Alcoholic dementia comprised cases in which marked mental deterioration and decay of intelligence and morality were the predominant symptoms and this occurred as the result of many years of more or less continuous use of strong spirits. Permanent mental deterioration was observed in all the cases studied. Among the various alcoholic psychoses were seen many cases resembling general paralysis, the exact diagnosis being possible only after prolonged observation—weeks or months. 10 per cent. of the total cases suffered occasionally from epileptiform convulsions, while suicidal attempts and acts of violence were common in all classes of cases—points of medico-legal interest. An alcoholic or an insane parentage was common and made the prognosis bad. Somatic and grandiose delusions with alteration of the sense of personal identity were unfavourable symptoms in delusional cases. In continuing the discussion Dr. Woodbury said that 90 per cent. of cases recovered from first attacks of delirium tremens. Dr. Philip C. Knapp said that in the wards and clinics of the Boston City Hospital cases of delirium tremens, hallucination, and alcoholic dementia were fairly common, while paranoid forms were quite rare. Dr. Mitchell, in reply, said that alcoholic pseudo-paresis resembling general paralysis was fairly common. Such patients had sluggish pupils which, however, reacted to light. Inequality of the pupils and failure of the reflex to light were found practically only in cases which had had syphilis. The delusional or paranoid cases in his series amounted to nearly one-fifth of the total. Parental intemperance was a common etiological factor. The milder forms of alcoholic psychosis occurred in early life frequently in association with habits of drinking. Alcoholic dementia showed itself in middle age or later and was the result of heavy and continuous drinking for many years.

SEÑOR MANUEL GARCIA'S CENTENARY.

IT has now been definitely arranged that on the date of the centenary, Friday, March 17th, a celebration will take place at noon in the rooms of the Royal Medical and Chirurgical Society, 20, Hanover-square, London, W., in the course of which His Excellency the Spanish Ambassador will convey to Señor Manuel Garcia the congratulations of the Spanish Government. This will be followed by the presentation of an address on the part of the Royal Society, before which Señor Garcia almost exactly 50 years ago read his paper entitled "Physiological Observations on the Human Voice," in which the invention and the method of application of the laryngoscope were described. Other addresses on the part of musical bodies, old pupils of Señor Garcia, and various laryngological societies will follow. So far as is known at present, the Berlin, South German, French, Dutch, and Belgian laryngological societies will be represented by special deputies. In conclusion of this part of the celebration Señor Garcia's portrait, painted by Mr. John Sargent, R A., and presented by admirers from all parts of the world, will be handed to him, together with an album containing the names of the subscribers. In the afternoon the London Laryngological Society will hold a special meeting at which the foreign delegates will be present and in the evening a banquet will take place, probably at the Hotel Cecil, in which all those who wish to do honour to the distinguished guest on the occasion of the hundredth anniversary of his birth will join. The banquet will be attended by ladies. Further particulars will be given when the time approaches.

THE ETIOLOGY OF CARCINOMA.

WE publish in another column an article by Dr. W. Ford Robertson and Mr. Henry Wade on the protozoon plasmodiophora as a cause of cancer in man, in which a further account is given of investigations already reported on at the meeting of the British Medical Association at Oxford on July 28th, 1904.[1] The writers claim for their work that it has yielded confirmatory results along three parellel lines: (1) in a series of figures presented by stages in the life-cycle of the plasmodiophora brassicæ in turnips; (2) in a series of figures of intracellular and intranuclear inclusions found in carcinomata in man; and (3) in the stages in the life-cycle of an organism which they claim to have cultivated from such tumours. The account of the investigations themselves leaves nothing to be desired in the pains which have been taken to conduct them in accordance with the demands of scientific accuracy. Hence it is all the more regrettable that the writers have omitted to establish the justice of their *a priori* position that cancer is a parasitic disease and the tenability of their working hypothesis that carcinoma is dependent upon the growth of a parasite of the same class as that which causes "finger-and-toe" disease in turnips. If the analogy between the processes of cancer and of "finger-and-toe" disease in plants be admitted, their observations on the similarity in the intracellular inclusions in the two diseases are entitled to rank as an important contribution to human knowledge. No attempt is, however, made to draw any parallel between the two diseases. In "finger-and-toe" disease an intracellular parasite lives in the turnip cell till it has no longer need for its host and finally devours it. The efforts of the turnip to make good the ravages are not demonstrated to be analogous to the ceaseless proliferation of carcinoma cells which are not produced to replace any known defect. In the absence of any proof of the correctness of the primary conjectures, the very careful observations to which they have led lose much of their significance. Previously to the writers' first contribution the claims of protozoon parasites of this class had already been subjected to searching examination. As a botanist who can speak with authority, von Tubeuf had protested against any analogy being drawn between diseases of plants of this nature and the carcinomata of man. As a pathologist Lubarsch, after experimental inquiry, had likewise declared no analogy to exist. Dr. Robertson and Mr. Wade have not attempted to meet the objections which have already been raised to the etiological significance which they attribute to the plasmodiophora, nor have they attempted to show that the processes of growth in "finger-and-toe" disease in turnips present a parallel to those of carcinoma. Until these deficiencies are removed and the results are amplified by experiments, a discussion of the similar appearances described in three parallel series of observations is out of place and the general importance of these careful investigations cannot be properly estimated.

---

[1] THE LANCET, August 13th, 1904, p. 469

PUBLIC HEALTH OF THE ROYAL BOROUGH OF KENSINGTON.

IN his recently published summary of vital and mortal statistics for Kensington during the year 1904 Dr. T. Orme Dudfield, the medical officer of health, supplies a variety of interesting information relative to the public health of the borough. The estimated population of the borough at the middle of the year was 178,500. The births registered were 3448, being 117 fewer than in the year 1903. The birth-rate, which of late years has always been considerably below that of London as a whole (27·8 per 1000 in 1904) has been declining since 1868, in which year it was 33·1 per 1000. In 1904 it was 19·3 per 1000, which was 1·5 below the decennial average and was the lowest recorded. In North Kensington—i.e., the part of the borough north of Holland Park-avenue and High-street, Notting Hill—the birth-rate was 27·1 per 1000; while in South Kensington—i.e., the part of the borough south of the streets named—it was 11·0 per 1000. The "crude" death-rate was 14·2 per 1000, which was 2·4 below the rate in the metropolis as a whole. The death-rates in North Kensington and South Kensington were 17·7 and 10·5 per 1000 respectively. In some other features, such as the infantile mortality and the mortality from zymotic diseases, the relative unhealthiness of North Kensington also appears. Inquests were held in 203 cases. There were no uncertified deaths. It is satisfactory to find that there is an increasing use of the public mortuary: 332 bodies were deposited in it as compared with 295, 279, and 304 in the three preceding years. The chapel of rest for the dead, situated at Avondale Park, was informally opened on June 23rd when the first body was admitted to the mortuary chamber. The number of bodies received to the end of the year was 26. It is to be expected that as the people become better acquainted with the accommodation provided for the reverent care of their dead the building will be used more extensively.

THE INFLUENCE OF HÆMORRHAGE ON THE COMPOSITION OF THE BLOOD PLASMA.

IN a paper read before the Philadelphia County Medical Society on Nov. 9th, 1904, and published in the proceedings, Dr. Thomas Stotlesbury Githens records the results of experiments the object of which was to determine which of the proteids of the blood plasma is nearest to the form in which proteid is absorbed and how the proteids are influenced by varying conditions. The method adopted was to draw blood from the femoral artery of dogs directly into a solution of sodium oxalate in salt solution, centrifugalising, and then separating the proteids by the method of "salting out." A quantity of blood was withdrawn on four or five occasions at intervals of several days and was examined as described above. The results obtained were that the fibrinogen steadily decreased in the successive samples, the serum albumin increasing proportionately. From his experiments Dr. Githens concludes that of the proteids of blood plasma albumin stands nearest to the form in which proteid is absorbed and that it is therefore quickly replaced from the food proteids, while fibrinogen, being a more complex and specialised form of proteid, is more difficult to replace. Similar results have been obtained by other observers in dogs and snakes. An observation of some interest in this connexion has been made by Moll who found that blood plasma, after being made slightly more alkaline and kept at a temperature of 56° C. for half an hour, exhibited an increase in the percentage of globulin, from which it might be inferred that the change from the simpler to the more complex proteid can occur in the blood itself. The results are of interest in that they are what might have been expected from the composition and chemical properties of the blood proteids, and they constitute a noteworthy addition to our knowledge of the chemistry of the blood under varying conditions.

ON Dec. 19th, 1904, that day being the eightieth anniversary of the birth of Sir Peter Eade, M.D. Lond., his colleagues on the staff of the Norfolk and Norwich Hospital presented him with an address, accompanied by a birthday gift, in recognition of the high esteem in which he is held by them and of his valuable services to the institution during 47 years as one of its physicians.

THE Russian Institute of Experimental Medicine, says the *Sviet*, has announced a prize in the name of K. Th. Kasimir of the value of £100 to be awarded to the best treatise on the application of radium in the treatment of skin diseases and particularly external cancer. The prize will be awarded on Jan. 1st, 1908—i.e., Jan. 14th New Style.

THE distinction of Chevalier de la Légion d'Honneur has been conferred upon Dr. George Ogilvie, senior physician to the French Hospital.

AT the recent annual meeting of the Manchester Edinburgh University Club Professor A. H. Young, Victoria University, was elected President for the ensuing year. It is anticipated that at the next annual dinner Sir William Turner, K.C.B., F.R.S., Principal of the University of Edinburgh, will be the guest of the club.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Jan. 27, 1827.

Now every person knows that the stomach does secrete mucus and a peculiar liquor, but I do not see the sources of this; we see distinct sources in the intestines, but we do not in the stomach; at least I can't.

With respect to the *physiology* of the stomach, to the best of my knowledge and belief, Mr. Hunter was the first man who broached those opinions which are generally accredited, or have not till of very late been disputed, which is, that digestion depends upon the sufficient quantity of the liquid which the stomach secretes—of the gastric fluid, and that this liquor has the properties of rendering any nutritive matter solid, so that it should not pass through the *pylorus*, until it had undergone this peculiar solution by the gastric fluid. Well, if the white of an egg is given to a hungry dog, in a few minutes it will be as *hard* as if it had been boiled for hours. The juice of the stomach instantly curdles milk. Take the gastric fluid out of the stomach of a calf just born, and it has most curious properties; the little of that fluid that is in the stomach they dry in it, then dissolve it, and then curdle gallons of milk with it, as you all know. Then, as the fluid of the stomach has the power of dissolving that which is nutritive, the question is, why don't it dissolve itself, it is flesh? John Hunter would never boggle at an answer for that, and he says, that the life of the stomach preserves it. There is no chemical agent will act on it. Worms live in the stomach, and yet there is no doubt but that a meal of dead worms would form a very nutritive repast to a dog. But does the fluid ever dissolve the stomach? Yes, it does. The proof of this is, that if a man eats a large meal, and is suddenly afterwards killed by a blow on the head, as has often occurred, you will see that the gastric fluid is acting, not on the food, but on the stomach, that it makes a hole in the stomach, and that the food gets through that hole into the belly. Various stomachs have been examined having these appearances. But Sir Astley Cooper told me of a case where a person was met with after death under these circumstances: the body was laid in what they would call *a very ungain attitude;* it laid with the thorax lower than the abdomen, and upon opening the body, the stomach was found to be dissolved at its *lesser* arch; it is usually at the *larger* arch where it is dissolved; in that case the diaphragm was dissolved, and the stomach was in the lower part of the thorax.

Some people say there is no gastric juice; why? Because we cannot get it. And why can't we get it? Because it is not secreted but at certain times; it is only secreted when it's wanted. There are many who think even now, that it's the *vital powers* of the stomach, and *not* the *liquid* that causes the digestion. Well, they may entertain that notion if they please, but all I am bound to do is, to tell you what appears to me to be the most reasonable physiology.[1]

---

[1] Excerpt from Mr. Abernethy's Physiological, Patholgical, and Surgical Observations, delivered in the Anatomical Course of Lectures at St. Bartholomew's Hospital.

West Cornwall Infirmary, Penzance.—The thirty-second annual meeting of the subscribers to this institution was held on Jan. 18th, under the presidency of the Mayor. The medical report stated that during 1904 the out-patients numbered 1698, and the in-patients were 111, both figures being slightly less than those for 1903. 60 patients were sent to the Bolitho Convalescent Home. The financial statement showed that the total expenditure was £912, while the total income amounted to £869. The committee in its report states that good progress is being made with the erection of the new infirmary. The committee, at the suggestion of Mr. F. Bolitho, decided that on the completion of the new building the members of the medical profession practising in Penzance should take their respective share of hospital work.

ARMY MEDICAL ORGANISATION IN BAVARIA.

By F. Howard, M.D. St. And.,
COLONEL, ARMY MEDICAL STAFF (RETIRED).

There are 30 military hospitals in Bavaria for the treatment of those patients who cannot be attended to in barracks. These hospitals serve to complete the education of the sanitary staff and are also used for the administration of stores and sanitary appliances. They are usually under the direction of the most senior military medical officer of the garrison, who has the chief command of the establishment; the patients are treated by the medical officers under him and by their assistants. These medical officers are all taken from the garrison. A medical officer does duty at a hospital for one year. Half of the orderlies belonging to the garrison troops and the orderlies belonging to the hospital are on the medical (sanitary) staff. The number of medical officers at a military hospital depends on its size, as does the staff of orderlies on the number of patients. One non-commissioned officer and one orderly are usually allowed for 20 patients.

The field hospitals are, as in other armies, set apart for the reception of wounded from the battle-field or from first-aid stations. The staff and *matériel* of these hospitals can be used for direct service on the field of action. If circumstances demand it the field hospitals can be utilised for other patients than wounded men. Each field hospital can treat 200 men without extra aid and can be divided into two sections each capable of acting independently. The chief surgeon commands the field hospital. There are 12 field hospitals for each army corps, distributed to divisions according to needs. Every reserve division has four field hospitals.

The ambulance service is undertaken by the sanitary companies, called sanitary detachments, which establish places for first aid, search for the wounded on the field of action, and carry them to the field hospitals. To a division of infantry there may be one or two sanitary companies, while a reserve division has one. There are no special detachments of bearers.

To each battalion of infantry, chasseurs, pioneers, and artillery on foot, for every cavalry regiment, and for every detachment of field artillery there are two medical officers. One sanitary non-commissioned officer and four bearers attend every company, battery, or squadron. On the lines of communication there are field hospitals within the sphere of the "Etape" inspection, "Etape" field hospitals and war hospitals, the staffs being regulated by their size and the special work to be done, the staff being furnished by the staff of the field hospitals, and the *matériel* by the reserve depôts of the field hospitals. Reserve hospitals are established within the sphere of the occupying army in addition to already existing garrison hospitals.

The following table gives the numbers, ranks, pay, and allowances of officers[1]:—

Staff.	Number.	Pay (marks).	House allowance (marks).	Lodging allowance (marks).	Horse allowance and forage for horses
Surgeon - General of the Army (Generalstabsarzt)	1	9000 to 1900 charge allowance	1500	1620	Horse allowance and forage for 3 horses
Surgeon - Generals (Generalaerzte)	3	1 with 7800 2 with 7200	540 to 1200	594 to 1314	Horse allowance and forage for 2 horses
Colonels (Generaloberaerzte) ...	6	6000	420 to 900	432 to 972	Forage for 1 horse
Lieutenant-colonels (Oberstabsaerzte)	58	29 with 5850 29 ,, 5400	420 to 900	432 to 972	Forage for 2 horses for mounted corps.
Staff surgeons (Stabsaerzte)	66	33 ,, 3900 33 ,, 2700	420 to 900	432 to 972	Ditto.
Surgeons (Oberaerzte)	51	1500	216 to 420	288 to 540.	Ditto
Assistant surgeons (Assistenzaerzte)	74	900	216 to 420	238 to 540	Ditto

---

[1] See La Medecina Militar Española, April 10th, 1904.

The numbers given are over and above the medical men who, on account of compulsory service, do duty as one year men in subordinate medical establishments.

The proposals for the Army Medical Department in Bavaria were agreed to without discussion for the financial year 1903-04. The proposed cost for the department, including cost of medicines, pay of pharmaceutical assistants, and so on, would reach the sum of 1,408,415 marks. Notwithstanding certain economies, nothing has been withdrawn which could interfere with the desire to attract the best men to the corps and to maintain a high scientific standard. For study allowances for junior medical officers fit for promotion some 25,500 marks are voted and for the military medical academies of the reserve classes some 10,250 marks. Some 12,000 marks go to allowances for professors and travelling expenses of those who study at the academies. While actually employed all officers of the medical department study for a fixed period before each grade promotion. The practical examination takes places during the manœuvres. Some 15,092 marks are allotted to anatomical museums, models of sanitary *matériel*, &c., and as in Germany no academy or institute is unprovided with a library 5600 marks are for the military medical libraries which, not like the Spanish, contain new instead of old books, very few classics, and a large number of reviews and monographs in various languages.

There is a supplementary vote of 2,271,740 marks for the construction and repair of pavilions in the military hospitals and 65,000 marks for field sanitary *matériel* which is to be of the most up-to-date type. Every year, or almost every year, supplementary votes up to 490,000 marks go to this object. The Germans always recognise that the army in *time of peace is a preparation for war and that the Army* Medical Department is very much more than a corps of mere hospital assistants.

TWELFTH ANNUAL REPORT (FOR 1903) OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

IN a leading article in THE LANCET of Jan. 21st on the annual report of the county medical officer of health we discussed certain administrative changes that had recently been *effected in the public health department* at Spring-gardens, changes which we believe to have been absolutely necessary in order that the purely sanitary work of the Council might be coördinated with the new educational functions which have devolved upon that body in consequence of the dissolution of the London School Board.

We now proceed to consider that section of the county medical officer's report which treats of the prevalence of epidemic and infectious disease in London during the period to which it relates. It will be remembered that in each of his successive annual reports since 1889, in which year powers were acquired for the compulsory notification of infectious disease, Sir Shirley F. Murphy has published uniform statistics concerning the age and sex-incidence of attack *and death by the notifiable diseases, together with* appropriate remarks on the measures necessary for their control. In his present report he has summarised the information collected during the last 14 years, and in a useful chart has shown the mean distribution of six of the most important of these diseases in each week and month of the year. This chart usef[illegible] and [illegible] 189[illegible] prese[illegible] to the death-rates but to the rates of attack by the several diseases. Moreover, Sir Shirley Murphy's chart deals with a more recent period—in fact, with the entire period that has elapsed since the publication of Dr. Ogle's diagrams, and on both these accounts it will be the more interesting [illegible] pidemiology. [illegible] to reproduce this chart [illegible] the following table whic[illegible] gives the principal information graphically illustrated in th[illegible] chart—namely, the mean relative incidence of attack by the several diseases in successive months of the year:—

Month.	Small-pox.	Scarlet fever.	Diphtheria.	Enteric fever.	Erysipelas	Puerperal fever.
January	8·3	6·6	7·6	7·5	8·3	9·9
February ..	13·0	6·0	7·6	6·0	7·3	9·2
March .. .	13·9	5·8	7·0	5·0	6·6	6·9
April .	13·4	6·1	6·5	4·4	6·8	7·2
May .	12·6	7·2	7·6	4·8	7·2	7·7
June . ..	9·8	8·1	7·8	5·8	7·2	7·2
July.	6·4	9·6	9·0	6·5	7·8	7·1
August	5·4	8·6	7·8	8·0	7·9	7·3
September ...	3·7	10·8	9·3	12·3	9·3	7·8
October . .	2·7	12·7	10·9	14·6	11·1	9·9
November ..	5·2	10·7	10·1	14·5	11·2	10·3
December	5·6	7·8	8·8	10·6	9·3	9·5
Total .	100	100	100	100	100	100

Being based on the aggregate notifications of 14 years in a population approaching five millions, the London practitioner of medicine may rely with some confidence on the figures here given as representing the probable future incidence on season of the several [illegible]

As in former reports, we notice [illegible] the excess or diminution in th[illegible] important diseases causing death in the administrative county *as compared with the corrected annual average in the* previous ten years From this table we see that with two exceptions the mortality from every one of the 20 diseases included therein has declined, in most cases considerably. Following upon two years of epidemic prevalence the inci[illegible] sligh[illegible] the c[illegible] to or[illegible] effec[illegible] larg[illegible] did r[illegible] was [illegible] provincial towns, more than 4000 cases being notified in one or other of them during the quarter, whilst only 74 cases occurred in London. It is, therefore, not surprising that infection was *repeatedly* imported into London from the provinces, but in addition to this we learn that it was from time to time introduced from abroad.

Although the mortality from measles in 1903 was below the decennial average, London nevertheless suffered more severely from that disease than did the great provincial towns, with four exceptions. In the course of the year 1903 the order of the London County Council came into force, extending to measles certain legal provisions for the prevention of infectious disease, except the requirement of notification. Whether or not the new order leads to the giving of more prompt information concerning absentees from school on account of measles is a question as to which there exists much difference of opinion. To what extent it is possible under existing conditions to limit the spread of measles cannot yet be stated generally but it is as well *to note* that many metropolitan medical officers of health regard the new powers with satisfaction. They recognise the value of these powers as an educational influence in [illegible] of measles upon parents [illegible] from the common practice [illegible] that disease to come into contact with their [illegible] ough during the holidays the chief source of information, that of the school, is wanting, Sir Shirley Murphy provisionally approves of the Council's new order, the effects of which are being carefully watched by certain of his medical colleagues.

In proportion to population the cases of scarlet fever notified in 1903 were fewer than in any previous year since 1891; the case mortality among the reported cases was also considerably below the average. If the mortality of scarlet fever [illegible] not in terms of cases notified but as a [illegible] ould appear [illegible] 1903 than [illegible] owns except West Ham, Hull, [illegible] on the low fatality (2·9 per-cent. of the attacks) and on the low case-rate of scarlet fever in 1903, Sir Shirley Murphy recognises the mildness of the disease in London. With diseases of this nature the difficulty of finding explanation for the occurrence of recognised cases is very great, inasmuch as mild unrecognised cases must often give rise to cases in which the symptoms are sufficiently pronounced for recognition, the source of infection being thus obscured. In a population such as that of London the chances of exposure to infection by unidentified cases are much greater than in sparsely inhabited districts; it is therefore satisfactory to record that Dr. G. Newman was able to trace infection to an antecedent case in 90 out of 283 cases occurring in Finsbury, whilst Dr. F. G. McCleary succeeded similarly in 96 out of 448 cases reported in Battersea. As in past years school influence was again powerful during 1903 in determining the spread of infection among children of school age. The effect of school closure during the holidays in interrupting the autumnal rise of scarlet fever in London is conspicuously shown in a diagram which may well be compared with the corresponding diagram for enteric fever, also included in the report; this diagram does not show any similar interruption. The table given above, which is based on experience in London during a long series of years, indicates the seasonal prevalence of scarlet fever; the months of September, October, and November are there shown to be the period of greatest prevalence and the month of March the period of least prevalence of this disease.

Diphtheria is another disease the prevalence, if not the fatality, of which is closely connected with attendance at school. Both the attack-rate and the case-mortality of diphtheria were lower in 1903 than in any year since 1891. The table shows a striking similarity in the seasonal incidences of scarlet fever and diphtheria, for which the only discernible cause is the common one of school infection. Sir Shirley Murphy gives the now familiar table showing the percentage increase or decrease of attacks of diphtheria in the four weeks of "holiday influence" (i.e., the thirty-first to the thirty-fourth week) in contrast with that in the four weeks respectively preceding and following the period of holiday influence; and with respect thereto he remarks that "the interruption of the autumnal rise during the period of the summer holiday previously referred to in the case of scarlet fever, is equally conspicuous in the case of diphtheria." In the year 1903 London experienced a lower mortality from diphtheria than did any of the great provincial towns, Leeds, Sheffield, and Leicester alone excepted. We learn that in the course of 1903 only a few localised outbreaks of this disease were observed, all of which were traceable to school attendance. In Paddington ten cases occurred among children attending a certain school, which was closed in consequence, with the result that no further cases occurred. In Chelsea seven cases occurred in a school, and in Finsbury seven cases in one school and ten in another, a relationship between which occurrences was established by Dr. Newman. Sir Shirley Murphy goes on to suggest that the appreciation of the part played in the dissemination of diphtheria by "carrier cases" must inevitably lead to a fuller examination of "contacts." Fortunately, as regards diphtheria, bacteriological methods are available for this purpose, and it is clear that the more completely the examination of "contacts" is carried out the more thorough will be the control over the extension of diphtheria. In a community like that of London the difficulties in the way of complete success are doubtless great. They need not, however, prevent steps being taken for the prevention of school attendance by children who although highly infective nevertheless present no clinical symptoms of the disease.

In proportion to population the reported cases of enteric fever in London were fewer in 1903 than in any previous year since the establishment of compulsory notification and the deaths were fewer than in any year since 1869, in which year deaths from enteric fever were first separately classified. The seasonal distribution of attacks was strikingly similar to the average, as shown in the table before referred to.

Among the articles of food mentioned as possible causes of infection by enteric fever are shell-fish, watercress, ice-creams, water, and milk. The extent to which contaminated shell-fish is productive of this disease in London cannot be determined. In some cases there is evidence of the ingestion of shell-fish being followed by enteric fever at an interval which corresponds with the incubation period of that disease; in other cases there is the additional evidence that the shell-fish had been obtained from polluted sources; whilst in others, again, the evidence does not amount to more than this, that a particular person suffered from an attack of enteric fever after eating shell-fish at some time within the limits of the incubation period.

In several instances it appears that persons who were notified as suffering from this disease had, within the incubation period, eaten either ice-creams or watercress. In Hackney two localised outbreaks were attributed by Dr. J. K. Warry to the eating of watercress. In one of these outbreaks 48 cases of enteric fever were reported and in the other 62. Inquiry as to the food-supply of the people in these affected areas led to the exclusion of all articles of food except watercress, and an inquiry as to the source from which several samples of the watercress were derived led to the discovery of serious contamination of the water in which it had been grown. The only instances in which attacks of enteric fever were attributed to milk occurred at Eltham; these, however, were few in number and were probably due to the admixture of polluted water with the milk.

(To be continued.)

THE CENTRAL MIDWIVES BOARD.

THE members of the Central Midwives Board met on Jan. 19th, at 6, Suffolk-street, Strand, Dr. F. H. CHAMPNEYS being in the chair.

The Board proceeded to consider under the provisions of the rules of procedure the proposed removal of the name of Miss Edith Gregory, a certified midwife, from the Midwives Roll, the charges alleged against her being that of signing false certificates in connexion with the training of candidates for the examinations of the Obstetrical Society of London.

Mr. G. W. DUNCAN, the secretary of the Central Midwives Board, stated the facts of the case. He pointed out that the matter came under the notice of the Board in consequence of a communication from the Obstetrical Society of London informing the Board that after consideration of the case of a certified midwife, Miss Edith Gregory, the council of the Obstetrical Society of London had resolved that her L.O.S. certificate should be forfeited. In the opinion of Mr. Duncan the charges against Miss Gregory rested on the reply which she had sent to the Obstetrical Society of London admitting that she had signed certificates required by nurses before admission to the examinations to the Obstetrical Society of London indicating that the nurses had attended not fewer than 20 labours, whereas, in point of fact, that number of cases had not been actually attended at the time Miss Gregory signed the certificates. Miss Gregory, however, pointed out that she understood that it was quite right to sign certificates so long as the nurses would have completed the number of cases before the examination took place.

In the course of the evidence that was offered in support of the charges against Miss Gregory it appeared that several years ago the Obstetrical Society of London was aware of the practice that certificates were signed for nurses *entering* the examinations of the society without these nurses having attended the required number of cases of labour, it being understood that the requisite number of cases would be made up to the proper total before the day of the examination.

Mr. C. E. GODWIN of the firm of Messrs. Godwin and Co., solicitors, Winchester, addressed the Board on behalf of Miss Gregory. In the course of his remarks Mr. Godwin stated that Miss Gregory had attended and supervised some 500 confinements and that throughout the whole course of these cases not a single septic case had occurred nor had a death taken place. That record, Mr. Godwin continued, was one which few could put before the Central Midwives Board. Miss Gregory was therefore a well-qualified midwife and if as the result of that day's proceedings her name was taken off the Roll the Board would be defeating the main object of the Midwives Act which the Board was called upon to administer. In regard to the number of cases attended by the nurses whose certificate Miss Gregory had *signed*, he *observed* that these nurses had attended a sufficient number of cases to be within a measureable distance of the number required and during the month ites and the examinations have been attended. It that Miss Gregory had deliberately signed these certificates with any improper intention. At the most it could be said that she was lax. Mr. Godwin concluded by declaring that there was no intention on the part of Miss Gregory to do anything wrong and he asked the Board to dismiss the charges against her. Of course the Board might consider it its duty to pronounce a warning in regard to the signing of certificates but he could not imagine that it would remove the name of Miss Gregory from the Roll of Midwives.

The Board then went into *camerâ* to consider its judgment and strangers were requested to withdraw.

Strangers having been re-admitted, Dr. CHAMPNEYS, addressing Miss Gregory, said that the Board had found her guilty of misconduct and had recommended that she should be cautioned as to her future conduct in signing certificates. The Board had decided, however, not to go to the extent of striking the name of Miss Gregory off the Roll of Midwives.

THE RUSSIAN CRISIS: ACTION OF THE ST. PETERSBURG MEDICAL PRACTITIONERS.

THOUGH we have every right to express the conviction that freedom is necessary to the progress of science, still it is not within the function and scope of this journal to deal with the political aspect of the terrible struggle now taking place in Russia. On the other hand, and without discussing the political issues raised, we may record that our medical colleagues in Russia have done what they conceived to be *their duty as citizens and this in spite of the great danger* which such action entailed. On Dec. 31st last, this being the anniversary of the foundation of the Academy of Medicine and Surgery, a banquet was held at St. Petersburg 300 medical men were present and many more desired to attend but there was not room enough to admit them. Dr. S. Elpatieoski was chosen as president of the banquet and made an appropriate speech. Dr. Mikhailovitch, Dr. Kokoujkine, Dr. Morgouliev, and others having also spoken, the medical men present had the courage to face the terrors of Siberia by adopting the following motions:—

[illegible]

Those present at the banquet then voted that the following telegram should be dispatched:—

To Professor Erisman (driven out of Russia in consequence of his liberal opinions and now professor in Switzerland).—The medical practitioners of Petersburg, to the number of 300, assembled at a [illegible]

A second telegram was sent to the Mayor of Moscow, Prince Galitzine, as follows:—

Deeming that the era of respectful silence is now and for ever [illegible] 's decisive and historic [illegible] and loudly express his [illegible]

The same telegram was sent to M. Moukhanov, President of the zemstvo of the Government of Tchernigov. Finally, a telegram of protestation and sympathy was sent to Dr. Zabonsov.

That the medical practitioners in associating themselves with the present upheaval, and this in so pronounced a manner, incurred serious risk has been proved by subsequent events. For instance, on the Saturday night previous to the massacre an influential deputation of literary men waited on M. Witte, Prince Mirsky, and M. Rydzeffsky for no other purpose than to implore that measures should be taken to avoid [illegible]

as a scholar enjoys a European reputation, is among these prisoners, and their offence, judged from the standpoint of Russian autocracy, is not in any way as serious as that committed by the 300 medical practitioners when they voted in favour of the above motions and telegrams.

THE PREVIOUS EXAMINATION AT THE UNIVERSITY OF CAMBRIDGE.

WE have received the following communication from a correspondent which we insert without necessarily endorsing *en bloc* the views therein contained.

"The changes in the Previous Examination proposed at Cambridge by the Studies and Examinations Syndicate, of which the President of the General Medical Council is a member, are exciting keen controversy within and without the University. They are intended to effect an improvement in the general scope of the examination which has to be taken by all candidates for medical and surgical degrees and also to open an alternative course for students from schools in which the ancient classics do not form the sole basis of instruction. It is known that to a large number of men who intend to follow the scientific and medical curriculum the present requirement of a modicum of 'compulsory Greek' is a serious hindrance. The 'Greek' is got up by a combination of 'crib' and 'cram' a month or two before [illegible]
tional or literary valu [illegible]
examination is passed. [illegible]
Greek and Latin shal [illegible]
German being allowed [illegible]
(2) that the test in English and English composition shall be improved, (3) that Paley's 'Evidences' shall cease to be a subject of examination; and (4) that two of the four school subjects—English history, experimental physics, elementary chemistry, and Scripture knowledge—shall be taken by all candidates. The mathe- [illegible] their recently altered form. [illegible] standard to be reached in [illegible] in German shall be raised above that which is now practicable. Set books are omitted and unseen translation with composition or translation from English are to be required. This will insure that the successful candidate has a real working knowledge of the languages of his choice, and remove the objection that an 'easy option' is offered to the non-classical. On the issue of the present controversy between reformers and anti-reformers depends the educational future, not only of the University, but of many secondary schools throughout the country. It will probably be decided by the vote of non-resident members of the Senate at a Congregation to be held next month. Medical graduates who are members and who sympathise in general with the proposed reforms are expected to visit the University in considerable numbers. A committee has been formed in support of the syndicate and is prepared to send to all inquirers detailed information bearing on the question. Applications should be addressed to Mr. A. C. Seward, F.R.S., who is tutor for natural science and medicine at Emmanuel College, and is acting as secretary to the Cambridge committee. He will be glad to receive the names of medical members of the Senate who intend to vote *placet*."

ASYLUM REPORTS.

London County Asylum, Colney Hatch (Report for the Year ending March 31st, 1904).—The average number of patients resident during the year was 2176, comprising 901 males and 1275 females. The admissions during the year amounted to 522—viz., 247 males and 275 females. Of these 418 were first admissions. Dr. W. J. Seward, the medical superintendent, states in his report that the admissions were 45 in excess of the number for the previous year. They included 41 cases of epilepsy and 33 of general paralysis, 29 of the latter being males. 57 patients were transfers received from other asylums and two were criminal lunatics brought from prison. With regard to the causes of insanity in the admissions hereditary influence was present in 27 per cent., 24 per cent. had suffered from previous attacks, 18 per cent. were due to alcoholic intemperance, and syphilis was ascertained to exist in a considerable number of cases. There were 29 patients whose age on admission was over 70 years. "Among the admissions there were 113 Jewish patients ......, and the present number of Jewish patients in the asylum is 304, being an increase of 35 since last year." The number of patients discharged as recovered during the year amounted to 197, comprising 76 males and 121 females, or 9·1 per cent. of the average number resident. The deaths during the year amounted to 258, or 12 per cent. as calculated on the same basis. Of the deaths nine each were due to cancer and epilepsy, 10 to organic disease of the brain, 13 to colitis, 14 to pneumonia, 19 to senile decay, 20 to cardiac disease, 32 to general paralysis of the insane, 41 to pulmonary and other forms of tuberculosis, and the rest to other causes. "The asylum has been very free from infectious disease. In May last (1903) two nurses contracted enteric fever and recovered, but no case of the disease has occurred during the last ten months." Colitis or dysentery was prevalent on the female side of the asylum till September, 1903, but since then "there has been a great diminution in the number of cases and there seems reason to hope that the epidemic, which commenced five years ago, is now practically at an end, but sporadic cases will probably continue to occur." Much important structural and sanitary work has been carried out, including improved ventilation of the staircases and the establishment of a new and complete system of electric fire alarms. The Commissioners in Lunacy state in their report that the general condition and management of the asylum were deserving of very favourable mention, that the day rooms were in very good order, clean, bright and comfortable, that the dormitories were wholesome and the bedding in good order, that all the exit doors of the wards were now made to open outwards with a view to facilitate escape in case of fire, that the condition of the patients was tidy, and that the medical case-books were intelligently and well kept. The committee of management states that it has under consideration the question of erecting permanent buildings to replace the annexe which was destroyed by fire. All the structures will be of ground-floor height and the cost of building is estimated at £70,000 exclusive of equipment.

London County Asylum, The Manor, Epsom (Report for the Year ending March 31st, 1904).—The average number of patients resident during the year consisted of 691 females. The admissions during the year amounted to 147 females. Of these 138 were first admissions. Dr. W. Ireland Donaldson, the medical superintendent, states in his report that the admissions were 48 less than in the previous year. The chief causes of insanity in the patients admitted were alcoholic intemperance and heredity, the former occurring in 32 cases and the latter in 41. The latter number is probably less than the actual cases of hereditary taint. In 25 cases the cause of the attack could not be determined, no history being obtainable. "The past year," says Dr. Donaldson, "has been a particularly free one from special disease, with the exception of dysentery, which, I am glad to say, seems to be on the decline, nine cases only having occurred, as against 18 in the previous year. I cannot but believe that with the opening up of the corridors—which took place last year to minimise the risks from fire—a great improvement in the health of the asylum, both among the patients and staff, will ensue, and although the past year is supposed to have been a very healthy one, I think that the small death-rate ...... was due in some measure to the very efficient system of ventilation which prevails in the asylum. ..... The health of the staff has been very satisfactory during the year, few cases of illness having occurred, and none at all attributable to the partly open corridors." The number of patients discharged as recovered during the year amounted to 50, or 7·3 per cent. of the average number resident. The deaths during the year amounted to 33, or 4·9 per cent. as calculated on the same basis. Of the deaths two each were due to diabetes and colitis, three to general paralysis of the insane, five to pulmonary tuberculosis, seven each to cardiac disease and pneumonia, and the rest to other causes. Fire drills for members of the staff continue to take place daily in the wards, and two men continue on night fire duty, one patrolling the corridors inside while the other walks outside. The villa for male patients has been completed and 47 patients were admitted in April, 1904. The Commissioners in Lunacy state in their report that the asylum appeared to be maintained throughout in excellent order, that the precautions against fire were ample, that the day rooms and dormitories were clean and well ventilated, that the behaviour of the patients was quiet and their personal condition comfortable, and that the medical case-books were well and regularly kept. The committee of management states in its report that the male villa will eventually accommodate 60 patients and that its cost and equipment have not exceeded £10,750. The erection of two more blocks to accommodate 60 female patients in each is under consideration. Alterations to corridors and the provision of additional doors at ward entrances to facilitate exit and to minimise the danger of fire have been completed at a cost of £3065.

Stirling District Asylum (Report for the Year ending May 14th, 1904).—From this report it appears that 255 patients were admitted into the Stirling District Asylum during the year under notice, but by the discharge of 74 patients "unrecovered" and of 89 "recovered" and the deaths of 92 the year closed with the same number on the books as at the commencement (684). This is a small resident population with an admission-rate of over 200, which rate is increasing This satisfactory state of things is to be placed to the credit of the boarding-out system. Dr. G. M. Robertson, the medical superintendent, states that during the last three years 203 patients who were unrecovered but who had become harmless and manageable have been removed from the asylum and the greater number provided for in the homes of their natural guardians. Amongst these, we gather, are the 74 referred to above. The advantage of this plan to the ratepayers is twofold, for the patients are maintained at diminished cost and there is no need to build or to extend institutions for their detention. Dr. Robertson analyses the admissions of alcoholic insanity for a period of years. It is stated that "the broad facts are substantiated that alcohol is the most important single factor in the production of insanity amongst men in this country" and that lately there has been "an enormous increase in the amount of alcoholic insanity." Dr Robertson agrees with the explanation which has been put forward as at any rate partly accounting for the recent increase in alcoholic insanity (now passing off), to the effect that the late war absorbed large numbers of able-bodied young men, who left the country and gave the lowest class of labourer a chance of employment and steady wages. "His sudden good fortune was too much for his powers of self-control." The excesses of this class made a substantial increase, we are informed, to the amount of alcoholic insanity admitted to the asylum. A feature of this asylum is the nursing system. In place of the usual asylum plan, according to which the male and female patients respectively are attended by persons of their own sex, the like principle being observed in respect to the head attendants, the method followed in the Stirling District Asylum is that of having female nurses in the sick and infirm wards of the male side, whilst the matron is at the head of the whole nursing staff. Under her are five assistant matrons, who are certificated hospital nurses, and whose presence in the wards, both male and female, is relied upon to maintain discipline and to set a worthy example. The same principle is adopted in night as well as day nursing. The Commissioners in Lunacy in the course of their annual reports refer in favourable terms to the nursing arrangements and to the results of the boarding-out system. These reports state that the fire-extinguishing arrangements are unsatisfactory, the pressure of water in particular being inadequate.

PLYMOUTH ROYAL EYE INFIRMARY.—The eighty-third annual meeting of the subscribers to the Plymouth Royal Eye Infirmary was held on Jan. 11th under the presidency of the mayor. The medical report stated that 2530 patients had been treated during 1904, as compared with 2285 in 1903. The financial statement showed that the income amounted to £1555, the expenditure being £1302. The committee states that the total outlay upon the new buildings had been £19,924 and at present only about £300 of that sum remain to be raised to make the institution entirely free from debt.

VITAL STATISTICS.

ANNUAL BIRTH-RATES AND DEATH-RATES FROM THE SEVEN CHIEF EPIDEMIC DISEASES IN ENGLAND AND WALES DURING 1904.

	Annual rates per 1000 living.			Infant mortality.—Annual death-rate of infants under one year per 1000 births.
	Births.	Deaths from all causes.	Deaths from seven chief epidemic diseases.	
England and Wales	27·9	16 2	1·94	146
Rural England and Wales	26 8	15·3	1·28	125
76 great towns	29 1	17 2	2 49	160
142 smaller towns	27·5	15 6	2·02	154

These rates are subject to revision.

We are indebted to the Registrar-General for the above death-rates for the urban and rural areas of England and Wales in the year 1904. We publish them for the information especially of medical officers of health who require these data for the compilation of their annual reports.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8405 births and 5419 deaths were registered during the week ending Jan. 21st. The annual rate of mortality in these towns, which had been 22·4, 19·9, and 17·5 per 1000 in the three preceding weeks, rose again last week to 18·1 per 1000. In London the death-rate was 16·6 per 1000, while it averaged 18·7 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·7 in King's Norton, 10·8 in Smethwick, 11·2 in Walthamstow, 11·8 in Leyton, 11·9 in Burton-on-Trent, 12·4 in Hornsey, and 12·6 in Bournemouth; the highest rates were 24·4 in St. Helen's, 25·0 in Hanley, 25·8 in Walsall, 26·0 in Grimsby, 27·6 in Swansea, 27·8 in West Hartlepool, 32·3 in Middlesbrough, and 32·5 in Merthyr Tydfil. The 5419 deaths in these towns last week included 358 which were referred to the principal infectious diseases, against 475, 399, and 378 in the three preceding weeks; of these 358 deaths, 92 resulted from whooping-cough, 88 from measles, 63 from diphtheria, 44 from diarrhœa, 38 from scarlet fever, 31 from "fever" (principally enteric), and two from small-pox. No death from any of these diseases was registered last week in Hornsey, Southampton, Reading, Great Yarmouth, Plymouth, Devonport, King's Norton, Warrington, Bury, Barrow-in-Furness, or Newport (Mon.); while the highest death-rates from the principal infectious diseases were recorded in West Ham, Hanley, Grimsby, Nottingham, St. Helen's, Salford, Preston, Stockton-on-Tees, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Leyton, Ipswich, West Bromwich, Grimsby, Nottingham, St. Helen's, Stockton-on-Tees, and Merthyr Tydfil; from scarlet fever in Northampton and St. Helen's; from diphtheria in Grimsby and Rochdale; from whooping-cough in East Ham, Bristol, Grimsby, Halifax, Bradford, and Sunderland; from "fever" in Salford; and from diarrhœa in Preston. Of the two fatal cases of small-pox registered in these towns last week one belonged to Burnley and one to Hull. The number of small-pox cases under treatment in the Metropolitan Asylums Hospitals at the end of last week was 18, against 17, 18, and 19 at the end of the three preceding weeks; one new case was admitted during the week, against five, one, and one in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2390, 2309, and 2192 on the three preceding Saturdays, had further declined to 2174 on Saturday last, Jan. 21st; 225 new cases were admitted during the week, against 201, 187, and 194 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 521, 443, and 301 in the three preceding weeks, rose again last week to 377, and were 22 above the number in the corresponding period of last year. The causes of 79, or 1·5 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Salford, Leeds, Hull, Cardiff, and in 39 other smaller towns; while the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Bootle, St. Helen's, Warrington, Manchester, and Barrow-in-Furness.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21·6, 20·6, and 21·6 per 1000 in the three preceding weeks, declined again to 20·1 per 1000 during the week ending Jan. 21st, but was 2·0 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·7 in Perth and 16·7 in Edinburgh, to 22·1 in Aberdeen and 24·5 in Greenock. The 674 deaths in these towns included 33 which were referred to whooping-cough, 17 to diarrhœa, 15 to measles, three to diphtheria, three to "fever" (including one case of typhus), and one to small-pox, but not any to scarlet fever. In all, 72 deaths resulted from these principal infectious diseases last week, against 78, 79, and 85 in the three preceding weeks. These 72 deaths were equal to an annual rate of 2·1 per 1000, which was 0·9 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 40, 37, and 45 in the three preceding weeks, declined again last week to 33, of which 27 occurred in Glasgow and three in Aberdeen. The deaths from diarrhœa, which had been 12, 13, and 16 in the three preceding weeks, further rose to 17 last week and included 12 in Glasgow and three in Dundee. The fatal cases of measles, which had been 20, 14, and 12 in the three preceding weeks, rose again last week to 15, of which seven were registered in Aberdeen, four in Glasgow, and three in Leith. The deaths from "fever," which had been eight and four in the two preceding weeks, further declined to three last week and included one fatal case of typhus in Aberdeen. The deaths referred to diseases of the respiratory organs in these towns, which had been 184, 182, and 183 in the three preceding weeks, declined last week to 156, and showed a decline of 11 from the number in the corresponding period of last year. The causes of 16, or more than 2 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·0, 25·6, and 22·6 per 1000 in the three preceding weeks, further declined to 21·2 per 1000 during the week ending Jan. 21st. During the past four weeks the death-rate has averaged 23·6 per 1000, the rates during the same period being 18 0 in London and 18·4 in Edinburgh. The 154 deaths of persons belonging to
under notice showed a
in the preceding week ar
to the principal infectious diseases, against five and 21 in the two preceding weeks; of these, five resulted from measles, two from scarlet fever, two from diphtheria, and one from "fever," but not any from small-pox, whooping-cough, or diarrhœa. These 10 deaths were equal to an annual rate of 1·4 per 1000, the death-rates last week from the principal infectious diseases being 0·9 in London and 0·5 in Edinburgh. The fatal cases of measles, which had been 16, three, and 12 in the three preceding weeks, declined again last week to five. The 10 deaths from diphtheria corresponded with the number in the preceding week, while the mortality from scarlet fever showed an increase. The 154 deaths in Dublin last week included 23 of children under one year of age and 44 of persons aged 60 years and upwards; the deaths of infants were nine below the number in the preceding week, while those of elderly persons showed no variation. Four inquest cases and five deaths from violence were registered; and 61, or nearly two-fifths, of the deaths occurred in public institutions. The causes of 12, or nearly 8 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

THE DIRECTOR-GENERAL OF THE INDIAN MEDICAL SERVICE.

Lieutenant-Colonel Gerald Bomford, I.M.S., C.I.E., has been appointed Director-General of the Indian Medical Service. He entered the Indian Medical Service as Assistant Surgeon in 1874 and reached the rank of Brigade-Surgeon-Lieutenant-Colonel ten years later. He served with the Perak Expedition in 1875-76, for which he was awarded the medal and clasp.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: A. Patterson to the *Vivid* and F. J. Lilly to the *King Edward VII.* Staff Surgeon O. Rees to the *Thames.* Surgeons: R. W. G. Stewart to the *King Edward VII.* and L. A. Baiss to the *Barham.*

ROYAL ARMY MEDICAL CORPS.

Major T. H. F. Clarkson has been appointed Senior Medical Officer, Jersey.

INDIAN MEDICAL SERVICE.

Major A. J. Macnab, joint civil surgeon, Simla, is appointed to the medical charge of the Army Headquarters Staff and establishments remaining at Simla during the winter.

VOLUNTEER CORPS.

Submarine Miners: The Mersey Division: Surgeon-Lieutenant R. Jones resigns his commission (dated Jan. 21st, 1905).

Rifle: 1st Roxburgh and Selkirk (The Border); Supernumerary Brigade-Surgeon-Lieutenant-Colonel G. H. Turnbull (Senior Medical Officer, Scottish Border Volunteer Infantry Brigade) is granted the honorary rank of Surgeon-Colonel (dated Jan. 21st, 1905). 4th (Stirlingshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant T. Beard to be Surgeon-Captain (dated Jan. 21st, 1905).

MENTIONED IN DESPATCHES.

In despatches relating to the operations in Northern Nigeria in 1903 the Acting High Commissioner states: "The medical staff consisted of Dr. H. P. Lobb and Dr. W. J. Healey, who were devoted to the care of the sick and wounded. I consider them both deserving of much credit."

THE NEW ARMY SCHEME.

We gather from what Mr. Arnold-Forster told a deputation the other day that it was impossible at present to commence the formation of territorial regiments. It appears that the number of short-service men in the army is so great that it is necessary to continue the long-service recruiting until a sufficient nucleus of long-service men has been obtained to insure the provision of drafts for India.

A RUSSIAN HOSPITAL SHIP.

We have received from a correspondent some notes of a visit which was made to the Russian hospital ship *Orel* in the month of December, 1904. The *Orel* was one of the volunteer fleet, was fitted up for hospital service in about six weeks, and, as could hardly help being the case, presented many of the objectionable features inseparable from the conversion of an ordinary vessel into a floating hospital. The operating room was abaft the captain's cabin on what a landsman would term the promenade deck. It was "all tiled in," was well lighted, and measured about 15 feet by 12 feet. Underneath it was a sort of waiting room for patients who, when their turn came, were taken up in a roundabout manner through the hatchways. A lift was provided but the patients could not be brought directly into the operating room on account of its position with reference to the wardroom used by the ship's officers. The cots were all in the space where the holds would ordinarily be. They were very close together, one above another, so that there did not seem to be much cubic space per man. Fans with overhead conduits were provided for the extraction of foul air but there was no forced admission of fresh air. The lower deck was just above the water-line and of course the scuttle would have to be closed at sea, so that on the whole it was probable that the atmosphere would be anything but good. Accommodation was supposed to be provided for 460 men, in addition to which there were 18 single cabins for officers and one larger cabin which would hold about six juniors. With that number of patients, however, there would certainly be great overcrowding. Apparently the refrigerating room was large enough and a sufficient daily supply of ice could be made. The cots were partly of English make and partly of French make, the former being preferred because they have springs. The mattresses were of French make, they were watertight, and, according to tests which had been made, each of them was capable of supporting seven men in the water. The method of taking patients on board seemed as if it would be very slow. They were to be placed in a perforated steel cradle which could be slung in a variety of positions; this cradle would then be hoisted in by a derrick and would be run along a little overhead rail. Good photographs of the *Orel* and of six other vessels belonging to the Russian Baltic fleet appeared in the *Engineer* of Jan. 20th.

THE WAR IN THE FAR EAST.

Public attention is no longer directed to the theatre of war in the Far East but has become focussed upon the stupendous events making up the tragic drama now going on in Russia. We are, as it were, seeing history in the very process of making and the present situation is a very remarkable one. Japan has found by far her most powerful ally in the internal condition of Russia and in the revolutionary spirit and disaffection which are apparently rapidly spreading throughout that empire. The unpopularity of the Russo Japanese war in Russia has furnished an occasion for a sudden outburst of deep-seated and long pent-up discontent on the part of its population. Be this as it may, the fact remains that it is now the state of Russia and not the war in the Far East that is uppermost in everybody's minds. There has been no change of importance in the Manchurian armies since we last wrote. There were, it is said, 15,000 disabled men altogether in the hospitals at Port Arthur at the time of its surrender, of whom 500 have since died.

The Irkutsk correspondent of the *Novoe Vremya* complains "that the hospital accommodation from Baikal to Omsk lacks comprehensiveness and only after ten months of war has the necessity for 80 fresh hospitals become recognised. The distance from the front indicates this section of the railway as the area for treating wounds in the second stage after operations. This is essential so as to obviate the neglect of orthopædic treatment of the extremities, as such neglect on a long journey causes many cases of inveterate, incurable contractions. It means returning many men to Russia unfit for work when such a result can be avoided. Many surgical, internal, and venereal cases are also imperfectly treated and there is a complete absence of Roentgen ray apparatus. Irkutsk, with its fine climate, is not fully utilised. It should be the headquarters for operations behind the base; but its dependence on Omsk causes apathy, misunderstanding, and friction. The fine doctors of the reserve who serve the Red Cross Society so well are stultified here."

The executive committee of the Red Cross Society proposes to sell scrip to the value of 400,000 roubles to meet impending outgoings in view of the insufficiency of ready money in the society's hands.

His Majesty's storeship *Humber* has left Hong-Kong carrying a fleet surgeon and medical stores and appliances for Wei-hai-wei, Port Arthur, and Dalny.

Major H. F. Cleveland, I.M.S., it is officially announced, has, with the consent of the Government of India, been appointed medical officer to the Amir and has on arrival at Kabul been cordially received by the Amir.

The Secretary of State has decided that the rates of half-pay of officers of the Indian Medical Service shall in future be the same as those laid down in the Royal Warrant for those of the same rank in the Royal Army Medical Corps.

MANCHESTER MEDICAL SOCIETY.—The annual meeting of this society was held on Jan. 11th for the election of office-bearers. Mr. W. Thorburn was elected President. Dr. E. M. Brockbank described an old MS. on Urines in the possession of the society, some pages being reproduced by lantern slides.

Correspondence.

"Audi alteram partem."

THE TREATMENT OF TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—In his admirable Bradshaw lecture[1] Dr. F. Foord Caiger has made a definite and weighty pronouncement in favour of the general adoption in hospitals of the cold-bath treatment of typhoid fever and this has been endorsed by a leading article in THE LANCET. Consequently it is to be anticipated that an extension of the system will result in this country such as has already occurred in so many other countries. In these circumstances it may prove of advantage to emphasise not only the potentialities but also the limitations of the treatment. Dr. Caiger has referred with approval to the results obtained in the Brisbane General Hospital. From May 15th, 1882, to Dec. 31st, 1886, a period of nearly five years, 1828 cases were treated expectantly: of these 271 died, a case mortality of 14·8 per cent. On Jan. 1st, 1887, the cold-bath treatment was introduced suddenly, every case that was admitted on or after that day being submitted systematically to a course of cold bathing similar in detail to that recommended by Brand. The only exceptions were: (1) a very few patients (practically limited to the first year) who refused to submit to it; (2) cases in which the temperature in the rectum failed to attain 102·2° F.; and (3) cases in which contra-indicating conditions, such as hæmorrhage, perforation, and extreme cardiac failure, existed. This course was pursued without interruption down to Dec. 31st, 1896. During these ten years 1902 cases were treated; of these 142 died, a case mortality of 7·5 per cent. The figures in both periods include all cases admitted to the hospital, even those which were moribund on admission and which, of course, were not bathed. Under the bath treatment, therefore, an improvement occurred in the hospital mortality of typhoid fever amounting to practically 50 per cent.—in other words, seven out of every 100 cases admitted were saved on the average through the alteration of treatment. Conformably, Osler says[2]: "The cold-bath treatment, rigidly enforced, appears to save from six to eight in each century of typhoid patients admitted to the care of the hospital physician."

The results obtained at the Brisbane Hospital were due unquestionably to the fact that the treatment was regarded from the very commencement as a prophylactic against the consequences of protracted pyrexia and not as a curative measure to be adopted in special cases. To obtain the greatest possible benefit from the treatment it is essential (1) that it [illegible] of the fever b[illegible] and (2) that all [illegible] be bathed, for [illegible] not possible to [illegible] and evolution of the disease.

It may be doubted whether in this country the fall in hospital mortality will be proportionate to that which occurred in Queensland. In Queensland the hospital accommodation is large compared to the population and a high proportion of hospital patients live in boarding houses and hotels, not in their own homes. Hence I am inclined to think typhoid fever patients seek and obtain earlier admission and it may be that a large number of mild cases are admitted into hospital. Nevertheless, the fall in mortality in this country should be marked; I do not think a reduction of from 15 to 9 per cent. would be an excessive estimate. The limitations to the treatment depend upon the fact that it has little, if any, influence to avert death from hæmorrhage or perforation. From August 1st, 1885, to Dec. 31st, 1886, 586 cases were treated expectantly. Of these 11 died from hæmorrhage and 17 from perforation. The percentage mortality of each accident to total cases was therefore 1·88 and 2·9 respectively, or together 4·71. Of the 1902 cases treated by cold bathing during the ten years from Jan. 1st, 1887, to Dec. 31st, 1896, 23 died from hæmorrhage and 56 from perforation. The percentage mortality of each accident to total cases was therefore 1·2 and 2·9 respectively, or together 4·1. The figures quoted refer not to the frequency of these accidents but to their mortality. Perforation is almost of necessity fatal; hence the distinction is here unimportant. But hæmorrhage results in death only in some 25 per cent. of the cases attacked; and there is reason to think that the slightly diminished mortality from hæmorrhage under cold bathing depends upon a slightly diminished fatality, not upon a diminished occurrence of this accident. The conclusion therefore is that the cold bath treatment exerts no effect upon the occurrence of hæmorrhage or perforation one way or the other and that practically the whole saving of life results from the reduction of the "pyrexial" sources of death.

The impotence of the cold-bath treatment to avert the occurrence of hæmorrhage and perforation has an important bearing upon the prognosis of typhoid fever in the two sexes. Under expectant treatment Murchison found the female case mortality higher than the male. This, he pointed out, was in spite of the undoubted fact that perforation is 2·3 times more frequent in men; in my experience much the same is true of hæmorrhage. Thus while men are more prone than women to succumb to the intestinal lesion the reverse is true to an even greater extent with regard to the pyrexia. It might be anticipated, therefore, that the bath treatment would influence more favourably the female than the male mortality, an anticipation which is fully borne out by statistics. Under expectant treatment 1160 males and 668 females were admitted. Of the former 164 died, a mortality of 14 14 per cent.; of the latter 107 died, a mortality of 16 per cent These results accord fairly with Murchison's figures. In striking contrast, however, were the results obtained under cold bathing. By that system 1188 males and 714 females were treated. Of the former 103 died, a mortality of 8·7 per cent.; of the latter 40 died, a mortality of 5·6 per cent. Thus while the male case mortality fell from 14·14 per cent. to 8·7 per cent., a reduction of 38 per cent., the female case mortality fell from 16 02 to 5 6 per cent., a reduction of 65 per cent. It would be easy to demonstrate that this much greater relative success obtained by cold bathing in women is almost entirely due to their comparative immunity from hæmorrhage and perforation.

It is satisfactory to read that Dr. Caiger disbelieves in the utility of giving astringents in the intestinal hæmorrhage of typhoid fever, and that he is inclined to think that drugs of the vaso-constrictor class, such as ergot and adrenalin, if they produce any effect at all tend to increase the bleeding. There is no doubt that adrenalin has prolonged hæmoptysis in some cases.[3] On the other hand, there is equally no doubt that the inhalation of amyl nitrite, the most rapid vaso-dilator known, is capable of immediately stopping hæmoptysis in the great majority of cases.[4] And there is good reason to anticipate that the same drug would be effectual also in hæmorrhage from the systemic arterioles. It is doubtful, however, whether amyl nitrite inhalation would be of use in the [illegible] typhoid fever since the action of [illegible] usually impossible to fix the exac[illegible] f bleeding. In one case Dr. R. B. Huxtable of the Charters Towers Hospital, Queensland, used amyl nitrite for severe typhoid hæmorrhage and the patient recovered. The only drug which is of proved value in typhoid hæmorrhage is opium given in full doses (40 to 60 minims of the tincture) as recommended by Broadbent. The patient should then be immobilised on a water bed and all food and drink stopped, except a little ice to suck. Intestinal hæmorrhage, except when it amounts to a mere trace before the tenth day of fever, and this only in cases where the date of onset is definitely known, necessitates the abandonment of bathing for a time. This enforced cessation of bathing frequently alters the whole aspect of the case. Quite commonly the patient now falls rapidly into the typhoid state, with high fever, delirium, dry brown tongue, sordes and tremulous muscles, and unless great care be taken a sacral bedsore commences and quickly spreads. This sudden change for the worse is the strongest evidence of the efficacy of systematic cold bathing in averting the typhoid state. The question as to how soon to resume bathing after the hæmorrhage has ceased is probably the most delicate and difficult of all the therapeutic problems presented by typhoid fever.

Unlike hæmorrhage, perforation demands the permanent suspension of bathing, and there can be no doubt that Dr. Caiger is right in stating that laparotomy, and laparotomy at the earliest possible moment, is in almost all cases the only correct procedure. Writing in 1897 I said:[5] "There can ...... be little doubt that the treatment of perforation, in hospitals at any rate, will in future be mainly by laparotomy; and that those hospitals in which the routine treatment is by systematic cold bathing will provide by far the largest supply of *suitable* cases for this operation." The reason for this is clear. "Systematic bathing ...... has so altered the symptoms of this accident and rendered so certain the possibility of its immediate diagnosis that the whole question of treatment requires reconsideration. Under expectant treatment the diagnosis is not infrequently impossible at the time. At the Brisbane Hospital up to the end of 1886 it was not uncommon to find perforative peritonitis for the first time in the post-mortem room. ...... In contrast to this is the experience of the Brisbane Hospital during the first three years of the bath treatment. During this time 34 cases suffered perforation, but so clear was the mental condition in all these patients that in every instance they were able to fix almost exactly the time of the accident. Not only so, but they were able as a rule to give so significant an account of the onset, site, and character of the pain, that usually a positive diagnosis could be made even before the signs of peritonitis were apparent."

The history of many cases was a sudden pain in some definite part of the abdomen; later an access of vomiting with a concurrent exaggeration of the pain, indicating extravasation of bowel contents. And it was found that very often the administration of a hypodermic injection of morphia (one-third to one half grain) immediately after the commencement of the pain was capable of deferring the onset of vomiting for some hours. That is the opportunity for laparotomy in my opinion.

I am, Sirs, yours faithfully,
Francis Everard Hare, M.D.

THE TREATMENT OF STRABISMUS.

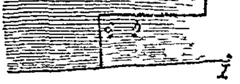
To the Editors of The Lancet.

Sirs,—As the brief account of my operation for strabismus, which appeared in The Lancet of Jan. 7th, p. 61, is not sufficiently clear to prevent the possibility of misinterpretation, I should like to supplement it by a few remarks of my own.

My principal object is to replace as much as possible tenotomy by the "advancement" of the muscles in the operation for all imperfections of the motility of the eyes (paralytic as well as concomitant squint, insufficiency, &c.). During last year I performed 100 "advancements," always with very good results, but in the same period I performed only two tenotomies.

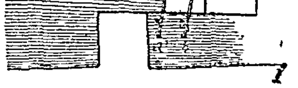
There are some rare cases of convergent strabismus of very old standing, with strong contracture (not contraction) and marked alteration of the structure of the internus muscle.

Fig. 1.



Lines of incision in muscle.
a, *b*, Points of suture.
i, Insertion of muscle.

Fig. 2.



Muscle advanced and sutured.
x, *y*, Gap in muscle. The remaining letters signify the *same as in* Fig. 1.

A surgical operation on this muscle seems to be admissible, simultaneously with "advancement" of the opposing muscle. Only, instead of setting back the shortened internus by a tenotomy, I propose to preserve its normal insertion on the eyeball and to lengthen it by a special procedure. The new operation consists in severing the muscle so that the divided extremities are left somewhat in the form of steps of a stair, as shown in Fig. 1, and lengthening it by uniting these extremities, as shown in Fig. 2. The operation has already given me excellent results.

I am, Sirs, yours faithfully,
Paris, Jan. 17th, 1905. Dr. Landolt.

THE PRINCIPLES OF TREATMENT OF PNEUMONIA.

To the Editors of The Lancet.

Sirs,—In a rather remarkable address on the Principles of Treatment of Pneumonia, published in The Lancet of Jan. 21st, p. 138, Dr. W. Ewart lucidly presents his views and his practice as derived from numerous and careful clinical observations and also from certain conceptions as to the pathological processes in the lungs and elsewhere. It is, of course, on this broad basis that all successful treatment must be reared and tested. Regarding the directing of treatment in conformity with what one conceives to be the pathology of the disease, this, though a most laudable ambition, is sometimes hazardous, and should no ill-results follow, the treatment may be right; but, on the other hand, the patient may recover in spite of the treatment. As to the indications for treatment which are supplied by the pathology of pneumonia I venture to notice briefly two of these, both of high importance, though differing widely in range. One of them is considerably exploited by Dr. Ewart; the other is not alluded to directly in his address but is suggested by his acute observations. That discussed by Dr. Ewart refers to the influence and import of the fibrinous coagulation in the lungs. He begins by quoting the opinion of a New York physician to the effect that "the extensive effusion of fibrin is really a 'breeding ground' for the diplococci and this enormous supply of pabulum is the explanation for the overwhelming amount of poison manufactured by them in the lung and thrown into the circulation." Then, in discussing the principles of action, Dr. Ewart advocates "defibrination," observing that "to discourage the local consolidation by diminishing the supply of fibrin factors is the end towards which our treatment and diet are made to converge." Further on it is explained that the consolidation is checked by administering citric acid, a precipitant of calcium which is essential to clotting. Other measures to this end are also advocated, including the possibility of impairing the solidification of the fibrin by withholding salt from the diet in view of the fact that the fibrinous exudation is rich in sodium chloride.

In studying the pathology of this disease for several years nothing more strongly impressed itself on my mind than the view that the pneumonic consolidation is nature's method of localising the morbid process and of curing the disease. The statement quoted by Dr. Ewart as to the fibrinous exudate forming a breeding ground for the pneumococcus belongs to the realm of fancy and is neither scientifically correct nor borne out by actual observation. In the first place, the fibrinous exudate is *dead*, in a state of coagulation necrosis, and so does not offer a suitable pabulum for the micro-organism. The organisms, imprisoned in this rigid dead substance, behave as they do in certain artificial media—viz., secrete an acid which quickly inhibits their vitality and their virulence. Some have supposed that this acid in the pneumonic lung is secreted by the pulmonary tissues and have termed it pneumic acid, but when engaged a few years ago in a research on this subject I extracted from pneumonic lungs an acid giving identical reactions to that obtained in artificial cultures. In examining microscopically sections of pneumonic lung in various stages of hepatisation I have been struck with the absence of active growth of pneumococci within the alveoli. Moreover, in cases of pneumococcus infection showing little or no tendency to pulmonary hepatisation; when the pneumococci run riot in the organism so to speak, the result is always grave and, indeed, generally fatal. Consolidation is doubtless the natural and wholesome reaction of the tissues to the disease, and though any attempt to modify the virulence of the organism and in this way limit the extent of the consolidation is not only justifiable but the object most to be desired, yet any interference directly, as by drugs, with the normal deposition of fibrin is, according to the view here propounded, simply to direct one's weapons against the *vis medicatrix naturæ*.

The other topic suggested by Dr. Ewart's address refers to the definitely scientific treatment of this affection in accordance with certain recent discoveries. Alluding to the objects of treatment, such as the arrest of the morbid process, the restriction of the invading host, and the neutralisation of the poison, Dr. Ewart remarks that the individual means to these ends may be inadequate at first or even mistaken. Inadequate doubtless, but perhaps not so much mistaken, provided our means are checked by the very definite method of blood examination which has been elaborated by Leishman and by Wright and Douglas. The amount of protective substances in the blood: those natural antitoxins which the latter observers have rather happily termed "opsonins," can be accurately estimated in any individual case of infectious disease and affords a true index of the patient's condition. The process is rendered both easy and speedy by the now celebrated method of Leishman, as modified by Wright. That the blood serum (not the corpuscular elements) contains a substance (an opsonin) which effects a chemical interaction with the bacteria so as to prepare the latter for phagocytosis seems to have been definitely determined quite recently by Wright and Douglas. In the case of two specimens of blood of conspicuously different phagocytic power the corpuscular elements were separated from the fluids and an interchange effected. "The leucocytes of the successfully immunised patient exhibited in these circumstances the lesser phagocytic action characteristic of the blood of the normal individual who served as a control, while the leucocytes of the normal individual exhibited the increased phagocytic action characteristic of the blood of the successfully immunised patient."[1] By counting the number of organisms (from an artificial culture) which the washed cells of normal blood when mixed with the patient's serum can ingest under certain conditions an accurate estimation can be made of the opsonic content of the blood. This phagocytic count is compared with the phagocytic count of normal blood, taken as unity,[2] and so from hour to hour or from day to day the rise or fall in the protective substances in the patient's blood can be accurately determined. Although at first sight it might be supposed that the results thus obtained would be capricious, yet repeated observations made in cases of acute and chronic infections show the method to be remarkably accurate. As already observed, this protective substance or opsonin is normally present in the blood, but when a vaccine is introduced into the patient's system its effect is to cause a greatly increased elaboration of opsonins by certain cells of the body. In the case of pneumonia we have no vaccine as yet which can be administered. But one can see that an attempt at a really scientific treatment of the disease would be made if the various methods of treatment adopted were considered in conjunction with the rise or fall of the opsonic curve. If, for instance, it was found that alkaline treatment was accompanied by a rise in the opsonic curve this would indicate that benefit was being derived, and *vice versâ*. In short, it might be possible [illegible]

---

[5] The Cold-bath Treatment of Typhoid Fever, F. E. Hare, 1898, pp. 186 et seq.

[illegible] lately on animals I found in certain cases the opsonic value of the blood falling without any loss of body weight or other clinical symptoms to indicate it. At any rate we have here opened up the possibility of treatment based on scientific data of a very precise character. It does not include the entire treatment of the disease, more especially as to the mechanical aspects, but it covers a very wide field and may in time displace the theorising and groping which up to the present have more or less characterised the efforts of the physician.

I am, Sirs, yours faithfully,
Henrietta-street, W., Jan. 21st, 1905. A. G. AULD.

ANKYLOSTOMUM DUODENALE.

To the Editors of THE LANCET.

SIRS,—Upon my return to Egypt I find that in a communication by Dr. Alessandrini to the Italian Zoological Society, written at the end of 1904, I am given the credit of having made independent research upon the question of the migration of the larvæ of the ankylostomum duodenale from the skin to the intestine. I also hear that other authors, such as Bentley and Z[illegible]n, seem to have accorded me similar credit. I therefore ask for a few lines of your valuable space to state that my two communications on this subject were written by Professor Looss's authorisation as a means of informing English readers of his now well-known discoveries.

I am, Sirs, yours faithfully,
Cairo, Jan. 12th, 1905. F. M. SANDWITH.

FRACTURE OF THE ANTERIOR FOSSA OF THE SKULL DIVIDING THE OPTIC NERVE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 21st Dr. F. J. Hathaway records a case of the above and it is commented upon in your annotations. Will you permit me to say that I discussed the same question in a paper before the Ophthalmological Society a few years since? I then recorded 18 cases and treated the subject somewhat fully in a paper which occupies 25 pages of the Transactions of the society for 1897. It is briefly abstracted in THE LANCET of June 26th, 1897, p. 1745. Since that time I have seen fully a dozen additional instances. Three cases a short while ago were attending my clinic at the same time and were shown at a meeting of the Sheffield Medico-Chirurgical Society. One case is at present among my out-patients at the Sheffield Royal Infirmary. I am not therefore disposed to consider the association of damage of the optic nerve with head injuries as particularly rare and, if looked for, such cases in a large clinic will not infrequently, I believe, be met with.

The medico-legal aspect of these cases is interesting and important. An individual meets with an injury to the head; there may be some loss of consciousness or not and the general symptoms pointing to severe head injury may or may not be marked but he asserts that he has thereby completely lost the sight of one eye. Examination with the ophthalmoscope only yields negative results. The lesson to learn from these cases is, I think, that one should be guarded in forming an opinion and should recognise the possibility of the patient's statement being correct. This will be corroborated, if true, after a lapse of a few weeks (three or more) by the decolouration which will be noticeable in the optic papilla. I referred to this matter in the paper I have mentioned and it has also been my habit to point out to my class for some years its importance. The absence of ophthalmoscopic evidence at the outset is doubtless due to the injury being posterior to the point of entrance of the central retinal artery into the optic nerve.

I am, Sirs, yours faithfully,
Sheffield, Jan. 23rd, 1905. SIMEON SNELL.

HESSING'S SPLINT AND CONTRACTURE AT THE KNEE.

To the Editors of THE LANCET.

SIRS,—I should be obliged if you would grant me space wherein to correct two omissions in my recent communication. First, the instrument I made use of was Hessing's splint-case appliance as modified by Hoefftcke. One of the modifications is a very important one and consists in an arrangement at the ankle whereby continuous traction of the leg is applied during the straightening of the knee. It is this traction which prevents the straightening process from causing pain. Secondly, I omitted to mention that the mobility of the knee, which at the commencement of treatment was almost imperceptible, has very slowly but steadily increased, being now some 15 degrees; in other words a flexed, rigidly ankylosed knee has been transformed into one with fair a [illegible] lity.

[illegible]

Wimpole-street, [illegible] [illegible] OPENSHAW.

WEST AFRICA AS A HEALTH RESORT.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if you would be good enough to contradict a report attributed to me that West Africa is likely to become a health resort. The health of Europeans in many of the coast towns now shows a marked improvement and will no doubt continue to improve. This is attributed to increased sanitation, including anti-mosquito measures, new residences in selected quarters, and more careful selection of those who go out and who, in consequence, realise how to live in a tropical climate and to avoid infection from malaria and other diseases, but it was very contrary to my wishes to imply that the improvement in health in West Africa is likely to be so rapid as is suggested by the remarks wrongly attributed to me.

[1] Proceedings of the Royal Society, Sept. 23th, 1904.

[2] In each case one volume of serum is added to one volume of corpuscles from citrated normal blood and one volume of a suspension of the organisms.

I am, Sirs, yours faithfully,

Liverpool, Jan. 24th, 1905. RUBERT BOYCE.

THE CAUSATION OF SEX.

To the Editors of THE LANCET.

SIRS,—In my letter of Jan. 7th I find I have inadvertently made a mistake in one of the dates given. Under "Child II." the letter reads, "last menstrual period ended Oct. 3rd, 1900." Obviously it should be, and was, Sept. 3rd, impregnation taking place between Sept. 24th and Oct. 2nd, that is, premenstrually to the next expected period, which, of course, did not appear, conception having occurred. I must apologise for the error and trust you will grant me space to correct it.

I am, Sirs, yours faithfully,

Jan. 22nd, 1905. *MEDICUS.*

MEDICAL NOTES FROM THE FAR EAST.

(FROM A SPECIAL CORRESPONDENT.)

(Continued from THE LANCET *of Oct. 8th, 1904, p. 1048.)*

WITH a permit from the Minister of War, twice extended, I presented myself at the chief division of the military hospital in Hiroshima on August 9th, 1904, and was escorted round the hospital by Dr. Tanaka, second officer in charge, who talked freely in German for three hours, on the condition only of our avoiding topics relating to strength and disposition of forces. Surgeon-General Professor Sato, principal medical officer of Hiroshima and professor in the Military School of Medicine at Tokio, was out at the time of my visit. Dr. Tanaka, however, who was called up for service after having formerly served for ten years in the army, has himself done all the operating and was the more able to give the required information through having been attaché to the British forces in South Africa in 1900, when he was unable to proceed further than Kronstad.

Hiroshima is the central base for all military cases of sickness or wounds from the front, as Sasebo is for all naval cases, as Moscow is for all severe Russian cases which are not too serious to be sent to Europe, and as Netley is for our army and Haslar for our navy on foreign stations in normal times. Since the journey hither from Dalny or Antung at the mouth of the river Yalu takes three days the most serious cases do not leave Manchuria and all have passed through the first and most interesting stage before they reach Japan. From Hiroshima all but the most severe cases are distributed to the large hospitals at Tokio or the smaller hospitals at Osaka, at Sendai, and in the north of the island of Kyushu. There is accommodation in Hiroshima for nearly 4000 patients, half that number being the total under treatment at the time of my visit. This hospital is organised in six divisions—six virtually independent hospitals, of which two were in existence and use before the war broke out, while the other four have been built and all six re-staffed for their present use. The method of building is the same as elsewhere, the material being grey unstained wood plastered on the inside and resting on brick foundations, the pavilions, of one floor only, being ranged parallel to each other down either side of a central covered alley way. Each pavilion consists of half a dozen separate rooms of good size for special cases, pack-store, dressing room, nurses' room, and kitchen, between which is the entrance to the main ward; the lavatory, bath, and latrine are in an annexe. In the pavilion in which special inquiry was made there were seven patients in three private rooms and 72 patients in the main ward, the nursing staff consisting of eight female nurses and one sister.

This ward was considerably overcrowded, as were several other wards, the division for the more serious surgical cases, over which Dr. *Tanaka took me most thoroughly, having* 300 patients but only 250 beds. The extra 50 patients, all well on the way to recovery, were accommodated in two ways, either by lying on bedding placed on the floor of one-half of the ward, the beds being cleared into the other half, or by three of them sharing two beds put side by side. To the first expedient there is no objection for convalescent surgical cases on the score of comfort, for the men are accustomed to sleep on the floor without even the intervention of a mattress. The only drawback is that as the windows are sash windows not opening lower than to within two feet of the ground, there is no cross ventilation except from the doors and the occasional inlets about six inches square at the floor level, and for comfort's sake ventilation with the temperature at 85° F. in the shade is highly desirable. The alternative of three convalescent surgical cases sharing two beds is not objectionable, at least for Japanese, on any grounds. The bedsteads are the simple old-fashioned iron ones with plaited iron laths, such as are hardly seen in England now even in servants' bedrooms. Put side by side they give ample room for three men who, wanting nothing more than a sheet to cover them even at night, have each their own upper sheets and are content. The windows of these older buildings are sash windows of glass but in all the recent temporary buildings the window openings are occupied by sliding screens of paper mounted on light wooden frames or by *shutters of thin imbricated wood hinged above so as to* open outwards and to give shade from the sun during the day-time. At night, however hot it may be, the Japanese are accustomed to close all doors and windows and to sleep almost stripped; indeed, the police insist on the houses being completely closed as a protection against thieves, and in the new Japanese hotel at Sasebo the difficulty of ventilation was supposed to be overcome by a foot of open lattice work above the sliding panels all round the room under the eaves of the roof. It was with difficulty that the hotel authorities were induced to leave the panels open all night and fortunately neither thieves nor police appeared to have noticed the omission. In the hospitals it seems that the wards are often entirely closed at night. In winter it is probable that they will to a great extent be closed all day as well, for the medical men are not free from the fallacious belief that the paper screens allow the transmission of sufficient air and the supply of artificial heat is likely to be inadequate. The spirit of hygiene has a very unequal foothold. The Japanese authorities are most careful to isolate dysentery, yet on a recent voyage of one of the hospital ships patients suffering from typhoid fever and dysentery were mixed together and there was no isolation of the cases of kakké (beri-beri), although there is at least as good reason for the isolation of that disease as of dysentery. Their arrangements in the field for the drinking of boiled water only are admirable but here in their permanent station hospitals, in their university hospital at Tokio, and in their new Red Cross hospitals the latrine system is extremely defective, ill managed, and often close to the water-supply. In the hospitals in Hiroshima there is no cover to the opening in the footboard which takes the place of a seat, so that the dust and flies from the fæces have free access to the wards. The receptacles are open pans fixed in the earth a foot or more below the board, and when they are to be emptied they are reached only with difficulty by a small opening on the outside at the ground level, through which opening the contents have to be ladled and scraped away with much soiling of all the surroundings. Perhaps it will some day be recognised that it would be better to provide the latrines with covers inside the building, to substitute half a kerosene tin for the fixed open pan, and to change it for a clean one every day. The medical staff for this division of 250 beds consists of six surgeons; the nursing staff consists of 66 Red Cross nurses, not counting, I imagine, the half dozen American nurses who came to Japan under Miss McGee, M.D., and who were still at work there at the time of my visit. The admiration of these American ladies for the nursing qualities and instincts of their Japanese colleagues was pronounced. At the mouth of the river Yalu hospital ships are compelled to anchor out of sight of land, the patients being brought out to them on sampans—the heavy punts of the East—worked by a stern oar. On reaching Japan the sick and wounded are again transferred into sampans at Ujina, the port of Hiroshima, and are taken up the two or three intervening miles by water. The vessel that had just brought back patients from the Yalu had a roll of 300 sick, a large proportion of whom were suffering from kakké (*beri-beri*). This disease appeared to be very prevalent and there were said to be 800 cases of it in Hiroshima. Dysentery was not at that time serious either in extent or degree.

Turning now to the clinical experiences in military surgery the first noticeable point was the collection of bullets and skiagrams. During the war in South Africa it was customary to give the patient the bullet or fragment of shell or bone extracted from his body under operation. In the Japanese hospitals however all such specimens belong to the Government and are systematically preserved in glass bottles or in a special glass covered and locked box divided into 100 compartments, each specimen being put into a separate compartment with a label briefly summarising the case from which it was taken. There is thus already both in Sasebo and in Hiroshima a museum of distorted bullets and of military pathology superior to any collection made during the South African War. A regulation to secure this result in all future wars should surely be added to the rules of our services both British and Indian. The new museum buildings at Millbank in London would thereby be improved in one respect in which they must be lamentably deficient. The Lee Enfield bullet measures 0 303 inch, or 7 57 millimetres, in diameter, the Russian 7 7 millimetres and the Japanese only 6 5 millimetres. In length and shape they are all much alike, with a very similar nickel mantle. The usual distortions were seen—namely, the marks of the rifling, side to side flattening especially at the forward end flattening with deviation almost to a right angle of the front half or third and ripping off of part of the nickel mantles. None of the bullets, however bore any sign of malicious manipulation there were no split, hollow nosed or filed bullets and no mushrooming had taken place in any of the fragments preserved. One bullet measured 12 millimetres (half an inch) across but it was duly cased. The one or two Japanese bullets present had been extracted from Japanese soldiers thus illustrating one of the practical difficulties of modern strategy. Pom poms appear to play no part in this war although there was a single instance of a one pound shell in the collection at Sasebo. Altogether Dr Tanaka has in three months performed 238 operations following the German principle by which the chief surgeon alone operates and junior men are only allowed to act as dressers and clerks. As with the bullets so with the skiagrams. Every skiagram as soon as it is printed is properly mounted on a card of uniform size with the chief particulars entered on the back and these cards are classified and kept in order in a special drawer on the principle of a card index. The skiagrams themselves however were not so good as those at Sasebo. There was no localising apparatus and the need of it was not felt. Skiagraphy is well known to have its limitations and Dr Tanaka like so many others has searched in vain for bullets localised just before operation by the cryptoscope or by skiagrams in different planes. He was well aware how obvious and yet how elusive a splinter among the metacarpal bones might be or a bullet in the soft parts of the thigh or a shrapnel ball in the buttock. What memorable and unwelcome episodes the bare mention of the fact must recall to those who worked in South African hospitals and to many who have practised in recent years in any large surgical centre.

The result of these failures is that at Hiroshima the surgeons have arrived at the rule for cases of buried bullet 'If in doubt do not operate.' In looking over the skiagrams the answer to my question as to operative treatment was very often 'None, he got well without symptoms.' 'Weak surgery' will be the verdict of the enthusiast but it is possible that here discretion is sometimes the better part of valour. It would be interesting to have a complete inquiry two or three years hence into the condition of wounds with retained bullets. Considering the aseptic nature of simple bullet wounds there is a good deal to be said in favour of the policy of letting sleeping dogs lie. With shrapnel there is more danger for shrapnel wounds are more prone to suppurate and it is noted at Hiroshima that on the average men wounded with shrapnel stay longer in hospital than those having gunshot wounds. But here also it seems reasonable if the surgeon and the patient prefer it to defer operation until symptoms appear. Prompt operation will however be indicated by the foreign body lying in such a region or position as to make danger or discomfort probable in the future. There was then in the hospital a case of this kind in which a shrapnel ball had entered below the right eye and penetrated through the malar bone into the temporo sphenoidal fossa where it was visible in a skiagram. An operation was performed similar to Rose's method for reaching the Gasserian ganglion by turning down the masseter and the zygoma and turning up the coronoid process of the jaw and the temporal muscle when the bullet was found lying absolutely in contact with the uninjured internal maxillary artery. Recovery is now complete. There were two inoperable cases of bullets embedded in the brain in which the symptoms were slowly improving. Another man had been struck by a bullet which entered his left eye and passed out through the right temporal bone just below the mastoid process. A fragment of bone came away through the naso pharynx and back of the mouth. Apart from the loss of his left eye he seems to suffer only from some deafness in his right ear; he stood at attention and showed us the site of his wounds as if they had been through his leg or his boots. There were three most interesting series of cases of which brief notes were made the respective lesions being gunshot wounds of the spinal cord aneurysms of various kinds and gunshot neuralgia. Each series would have repaid a lengthened study had circumstances permitted.

[Considerations of space necessitate the omission of our correspondent's remarks on wounds of the spinal cord. He also described one case of the somewhat rare condition in military surgery of subphrenic abscess and a case of nerve suture the only operation of that kind which had as yet been performed the musculo spiral was the nerve sutured and the effect was complete relief of recent terminal radial neuralgia. After the paragraphs on wounds of the spinal cord he continues as follows —]

The series of aneurysms was interesting from the point of view both of diagnosis and prognosis. The commonest wound of considerable blood vessels consists in the minute rupture of a large vessel or the larger rupture of a small vessel in a limb where extravasation of blood is limited by fascia and muscular planes the result being the formation of a false or spurious aneurysm. It is not necessary that the bullet should itself rupture all three coats. It is enough that it should rupture the outer coat and most of the thickness of the middle one allowing the inner coat to bulge through the wound. The intra arterial pressure will then gradually enlarge the true aneurysm thus produced especially if the wound appears to be simple and the patient walks from the site of injury to the hospital or ambulance or is allowed to walk about the hospital after admission. This shows the imperative necessity not always recognised by those unaccustomed to military surgery, of absolute rest for all patients with flesh wounds, however simple during the first few days. A slight wound of the arterial coats may otherwise lead to aneurysm the inner coat becoming spread out over an ever increasing accumulation of blood may give way, and even if the swelling be circumscribed and the limb kept at rest there will be serious danger of gangrene from defective arterial flow and from venous obstruction by the pressure of the extravasated blood. Nor is the danger passed after operation when the clot has been incised and turned out without much loss of blood and either end of the vessel successfully secured and ligatured. In Hiroshima there have been several cases of gangrene after operation mostly attributed by the operator to the exclusion of too great a length of artery—usually the femoral from the groin downwards—and the cutting off of too many branches from the collateral circulation. This gangrene has usually limited itself to the tips of one or two toes there were however one or two cases which were less fortunate. In all down to the end of July 1904—that is for a period of less than six months since the beginning of the war—there have been 21 cases of spurious aneurysm. The arteries affected have been as follows in the neck the vertebral artery the second part of the subclavian and the third part of the subclavian, in the upper limb the axillary artery the brachial the radial and the anterior interosseous, in the buttock the superior gluteal artery, in the lower limb the popliteal artery the anterior tibial and the posterior tibial. Two of the above cases of spurious aneurysm proved of special interest in operation. In one a bullet wound had been received on June 25th 1904. When the patient was admitted at Hiroshima on July 23rd a large swelling was found under the outer half of the clavicle bulging the pectoral muscles slightly forwards and transmitting arterial pulsation. On July 25th the usual operation for ligature of the third part of the subclavian was per

formed u … ntrol hæmorrhage and the artery so far

as could … the clavicle appeared

undamag … directly incised below

the clavicle, when the blood gushed out to an alarming extent despite the ligatured subclavian. The wound was instantly plugged with gauze and after much trouble, the pectoralis minor being reflected, the axillary artery was secured immediately above and below the site of injury. The aneurysm was spurious and a fortnight later recovery was already complete so far as could be judged. In the other case a bullet had passed in through the right eye and out just below and behind the angle of the right lower jaw. No symptoms were caused except, of course, those due to the pulped eye. Facial, temporal, and occipital pulses could be felt; cerebration was normal; and the superficial blood return of the neck was unimpaired, but there was a large tense swelling in the site of the wound of exit behind the angle of the jaw. The tumour was incised and profuse pulsating hæmorrhage took place from the depths of the wound, apparently arising from one of the important arteries of the neck. The wound was promptly tamponned with gauze and after infinite trouble the source of the hæmorrhage was traced right down to the transverse process of the second cervical vertebra, through which the blood was found welling up, obviously from a ruptured vertebral artery. At this depth it was impossible to reach the artery to tie it, even if the end could be found, and the patient had lost so much blood that further operation was inadvisable. The wound was therefore again tamponned and death unfortunately occurred next day, probably from cerebral clot.

There have also been several cases of arterio venous aneurysm but the Japanese surgeons have not yet had an opportunity of seeing the results of operation or non-operation under these conditions. At present, if there is a considerable swelling or definite symptoms—not including the mere buzzing sound—Dr. Tanaka ties the artery above and below, as a rule, leaving the vein untouched. Both Mr. G. H. Makins and Mr. A. A. Bowlby, however, in their books refer to the frequency with which apparently harmless arterio-venous aneurysms cause weakness and incapacity of a limb as soon as the patient returns to military duty or civil employment, and also to the fact that the difficulties of operation are increased by delay.

The third interesting series was one of gunshot neuralgias, 24 cases of which had been operated on by Dr. Tanaka. Neuralgia of the median nerve has been especially common and in nearly every case of this series definite cause for the neuralgia had been discovered and to some extent removed. Pressure by scar tissue, involvement in callus, subacute inflammation of surrounding parts leading to perineuritis and neuritis are the common causes, the most usual being inclusion in scar tissue. Operative treatment consists of neurolysis—another word for removal of the cause—and stretching so as to break down intraneural adhesions. The result is not immediately satisfactory to either patient or surgeon but there is a slow improvement which continues until in most cases the neuralgia is completely gone.

Of interesting visceral lesions notes were made of one gunshot wound of the thorax and one of the abdomen. The first was a case of hæmopyothorax. The wound of entrance was situated an inch below, and outside, the right nipple; the wound of exit was in the seventh intercostal space close by the angle of the right scapula. The injury was received on June 21st, 1904, and speedily healed on the outside. Intrathoracic symptoms were slow in manifesting themselves and the physical signs, variable in character and indefinite in extent, seemed only to indicate a subacute bronchitis of the right lower lobe of the lung and a slight dry pleurisy at the base in the flank with low fluctuations of temperature to 100° F. (38·3° C.). After a time pyrexia became more marked, dulness was made out in the sixth space in the posterior axillary line, pus was found on puncture with a needle, and an operation was performed on August 4th. On incision a localised collection of blood clot was discovered, broken down at the centre into pus. An inch of rib was resected and the wound was drained with sterilised gauze. As seen after a few days the drain had already been dispensed with, the temperature had fallen to normal, and the intrathoracic signs had disappeared. In the second case a man had been shot through the liver and had recovered without operation and without manifesting any symptoms of injury. The wound of entry was in the right anterior axillary line immediately below the costal margin, at about the tip of the tenth rib. The exit was immediately internal to the inferior angle of the right scapula as the patient stood at "attention." Both liver and lung must have been traversed, and apparently not only must the gall-bladder and the large vessels of both organs have escaped but the bullet must also have passed out through the seventh intercostal space behind, avoiding the ribs both above and below, for at no time had there been any local tenderness or any sensory disturbance. Notwithstanding the aseptic methods in use at these hospitals, the occasional occurrence of suppuration in fresh operation wounds was acknowledged. There were several cases of fractured tibia and fibula or femur all fixed in well-made plaster splints, those for the femur being continued as a spica round the waist and strengthened by a lateral iron. But I do not think there was a single case on extension; still less one on a Hodge's splint which appears to be unknown in Japan although it is, to many London surgeons at any rate, the ideal treatment for fractured femur.

From the foregoing it will be seen how thoroughly the Japanese practice conforms to the European, both in arrangement and management of the hospital, in nursing, in diagnosis, and in surgical and general treatment. They will, however, have to make very great reforms in certain parts of their sanitary administration. As a rule they have shown considerable ingenuity in adapting European methods to their own circumstances and their technical work compares favourably with that of any army or any hospital.

CHICAGO.

UNHEALTHY WORK IN THE STOCKYARDS.—SHAMELESS INDIFFERENCE TO THE INSANITARY CONDITION OF THE BUILDINGS AND THE CATTLE PENS.—POLLUTION OF THE SUBSOIL.—THE NEED FOR LEGISLATIVE INTERFERENCE.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from p. 185.)

THE statistics that have been given and the details concerning the housing of the population engaged at the stockyards indicate that whatever ill-health prevails in this community in excess of what might be expected in the ordinary course of events is due in all probability to the nature of the occupation of the workers. The objection, however, may be raised that such a difference is but slight and therefore is not worth troubling about. Where human life is concerned, however, such an answer cannot, of course, be accepted. Besides, looking closely into all the circumstances it does appear as if some three or four lives, if not more, are lost every year in every thousand of the population of Packingtown and that these lives would be saved if, instead of the present disgusting slaughtering and packing factories, proper abattoirs were built and placed under efficient sanitary control. Of course, the estimate of from 3 to 4 lives per 1000 per annum is but a rough conjecture, based first on the fact that the statistics seem to show an excess of more than 2 per 1000 on the average for the whole city and that the very exceptional amount of vacant space and open air enjoyed in Packingtown should result in giving this district a death-rate below the average for the city as a whole. Especially should the death-rate be lower in this the eleventh sanitary district than it is in the fifth, sixth, and fifteenth sanitary districts. As this is not the case, it is only natural to attribute the comparatively higher death-rate of the eleventh sanitary district to the unwholesome conditions under which the work is done in the stockyards.

Speaking to local practitioners, they told me that the stockyard workers suffered more especially from tuberculosis and diseases of the respiratory organs and also from rheumatism and heart disease. The latter complaints were especially noticeable among those who had constantly to enter the cold storage rooms. In another department the workers are affected by the dust of the bones that are ground to make buttons. Then there is a department where a considerable number of women pack tongues in tins. Just behind them these tins are soldered and this operation produces a great heat. Finally, and also close at hand, jets of steam are discharged into other tins so as to sterilise them. And yet not very far off there are cold storage rooms. Here, then, dangerous variations of temperature constantly prevail. A partition would protect some of the women workers from the steam, but no one seems to care and even so simple and inexpensive a device has not been adopted In some compartments it will be noted that the women often put their aprons over their heads On inquiry it was ascertained that they do this not to keep their heads clean but to keep off the damp Again there is a blue paint employed to colour the tins Fine particles of this paint are blown about and have *a distinctly irritating effect on the air passages which predisposes* them to more serious disease While many work in overheated and damp atmospheres, others are engaged in the chilly and cold storage rooms Such temperatures lower the resisting power of the mucous membrane in the air passages and increase the susceptibility to disease

In regard to tuberculosis, it was pointed out that there were so much blood, water, steam, and damp about that even if some of the workers suffered from pulmonary tuberculosis and did expectorate on the floor this could not dry and therefore could not be breathed by others because there is no dust in the atmosphere The atmosphere might have all kinds of unpleasant qualities but it did not contain any dust On the other hand, with the aid of steam, grease, and dirt which abound in these buildings the bacilli of tuberculosis are believed to be capable of multiplying rapidly and they may live for a very long time As for being taken up so as to come in contact with living human beings this is done by the boots of the persons going to and fro, by the pieces of meat which fall on the floor, by the carcasses, notably of the big cattle, which are deliberately laid on the floor, by the wheels of the trucks which roll over the floor, and by cases, tins, and boxes of all descriptions pushed and dragged about Then there are the rafters, the dark nooks, and the corners where all the conditions necessary to form good culture grounds abound Thus it is that tuberculosis is especially prevalent among the workers at the stockyards , and this is not only an important fact in itself but it gives rise to the increased possibility of the occasional introduction of the bacilli in the provisions which are sent from Chicago all over the world The condition of this great industry affects not only the health of the inhabitants of Chicago It is a local, but it is also a national, it is even an international, question Here is one of the largest amalgamations, trusts, or unions of various firms representing various branches of associated industries that exist in the world It has command of a great portion of the meat trade throughout the United States and threatens to become an absolute monopoly From America to all parts of the world large quantities of these Chicago prepared and preserved meats are exported If infection can be spread through meat then what a danger such an establishment might become to the world at large As already explained, anything like a thorough disinfection of the premises is impossible and is never attempted Nor can natural disinfection take place because daylight and the direct rays of the sun cannot reach the greater part of the interior of the buildings where the work is done, the meat is handled, and the tuberculous attendants expectorate That the surroundings are foul, that in any case there is something wrong in the conditions of the work or of the workers, is shown by the fact that the smallest scratch or cut will result in blood poisoning if the wound is not at once treated with a strong antiseptic Then there are the festering sores of the men who work in the ham curing department and who are constantly plunging their hands and arms in the brine It may also be noted that rendering vats are most dangerously placed The lids are on the level of one floor and the vat or tank is on the floor below If the lid is taken off there is no rail to prevent anyone falling in It is asserted that several persons have thus met with an awful death In these rendering vats the fat is converted into oil or oleo margarine and the steam escapes into the rooms where people work, adding to the unwholesomeness of the premises

Outside and all [illegible] -ttle, sheep, and pig pen [illegible] to a length of 25 miles [illegible] es in length so as to a[illegible] ogs, 50,000 sheep, and 5000 horses It would be thought that before allowing such an enormous congregation of living animals on one single spot the most elaborate precautions would have been enforced Yet the view given in the last article (Fig 7), taken from the window of the chief government inspector's office, shows that the cattle pens are made of wooden partitions which have not even been whitewashed Nor is this some out-of the way and neglected corner On the contrary, it is the most frequented part and close to the main entrance of the stockyards Of course the first step to be taken in planning such a cattle market would be to provide throughout an absolutely water tight flooring or paving Further, this pavement should be convex so as to drain automatically to small surface gutters gravitating to numerous gullies emptying *into very carefully built self cleansing sewers* Considering the enormous amount of manure which must accumulate in such a market the necessity of water tight pavement to prevent the contamination of the subsoil is self evident Nevertheless, and it will scarcely be credited, a large portion of the stabling and cattle pens is on bare earth The liquid manure sinks straight into the subsoil , no attempt is made to prevent this wholesale contamination Here and there, not to prevent contamination but to secure a better roadway, a firmer foothold, and to reduce the mud nuisance, a sort of rough wood pavement was put in This is made of trunks of trees cut horizontally and these little round logs are placed side by side This backwoodsman's expedient has now been replaced by the use of bricks but neither bricks nor blocks prevent the contamination of the subsoil

It is over the bare earth also that the railway cattle vans laden with livestock arrive and discharge their freight It does not seem to have dawned upon anyone that precautions are necessary At Berlin the space between the railway lines is carefully arched over with a brick and cement pavement Then along the lines there are water reservoirs built up at a considerable height to give sufficient pressure for cleansing purposes. When a train arrives after the cattle have descended on the pavement especially built for them the sand is swept or shovelled out of the vans What cannot be thus removed is washed out with a fire hose After that an attendant arrives with brushes and pails containing a hot 5 per cent solution of soda With this the inside of the cattle, hog, or sheep van is carefully scrubbed The State, as owner of the railways, pays two marks for the cleaning of each van Considering how much cheaper money is in America the payment should be at least one dollar for sweeping and washing out each cattle van whenever it reaches the central market at Chicago There is no reason why the American railway companies should not be as clean and as careful as the German State railway department Considering that more food is exported from Chicago than from Berlin such precautions are more necessary at Chicago than at Berlin Yet even by the main entrance of the stockyards there is no evidence of any such precautions Here in front of the principal gate (as shown in Fig 8 in the last article) are a large number of railway lines and with that carelessness for human life which is a disgrace to America the trains pass among the people walking in and out of the stockyards At Berlin many lines also converge to the cattle market and municipal slaughter house but there are fine iron overhead bridges, so that pedestrians may cross in all directions without any risk of being hurt by the trains At Chicago the cattle step out on the bare earth which they [illegible] Cattle runs have been constructed not [illegible] o provide inclined plains so that [illegible] walk up to the higher floors of the buildings where it is more convenient to kill them and to deal with their carcasses How such rough wooden structures can be kept in a proper state of cleanliness is another matter which has received little or no attention Pending their sale the animals have no suitable stabling provided for them

At Anderlicht, near Brussels, the stables for cattle awaiting slaughter are built with the same care as hospital wards Alike in the trough, floor, and ceiling no angles are allowed All is rounded off In no place can dirt accumulate Along the whole length of the mangers there is a water pipe so that they can be instantly flushed out The flooring, of course, is absolutely water tight and the ceiling and the walls can likewise be flushed with water from the fire hose With louvre windows on each side through ventilation is secured and the direct rays of the sun can penetrate into the stables Of course the slaughter house sheds are even more elaborately ventilated Not only do large windows face each other on both sides but there are lantern ventilators on the roof and openings on the floor level Where tripe is prepared the apex of the roof is opened along its whole length and cannot be closed Now the wholesale slaughter-house and cattle-market of Anderlicht form not a municipal or State establishment but a private enterprise, run for profit just as the stockyards of Chicago. The capital engaged is trifling as compared to that of the multi-millionaire monopolists of Chicago. Therefore, in the perfection of cleanliness and drainage, of scientific appliances, of bacteriological and well-appointed laboratories for microscope work, and of disinfecting apparatus the Chicago stockyards should excel far and away what is done in such places as Anderlicht. It may be considered only natural that the State or a municipality the first object of which is not profit but the health of the public and the welfare of its employés, should at least in some circumstances manage better than a private business undertaking. But at Anderlicht we have only private enterprise the main object of which, as at Chicago, is profit; yet Anderlicht presents to Chicago all the difference between civilisation and barbarism. This must be due, I cannot help repeating, to the absence of the sense of dignity which is one of the worst failings noticeable in America. So long as a thing pays it does not matter what ignoble expedient may be employed to make it pay. Some of the principal owners of the Chicago stockyards have confessed that they have more money than they know how to employ. Yet they allow a small enterprise like that of Anderlicht to put them to shame. Had they any sense of pride they would not be content to continue pocketing money made from filth but would feel intensely humiliated by the thought that not only had municipalities, both large and small, but even private enterprises succeeded in building and managing cattle markets and slaughter-houses where no filth accumulates but where there are light and air throughout, no subsoil contamination, and no promiscuity between the carcasses of diseased animals and meat intended for human food. Where at Chicago are the quarantine stables? where is the quarantine slaughter-house? where is the quarantine depôt for suspected or diseased carcasses? where is the quarantine destructor for the same? At Chicago all these dangerous services are mixed "higgledy piggledy" with healthy cattle and wholesome meat.

The mere fact that several European Parliaments have felt that the filthy ways prevalent at Chicago necessitated special legislation against importations from that town is such an affront that if there were any sense of dignity the whole nation would rise and insist upon the sweeping out of those truly Augean stables known as the Chicago stockyards. If this is not done there is ample vacant space in the immediate neighbourhood for the State or the Chicago municipality to build model slaughter-houses according to modern principles of sanitary science. Then a law could be enacted prohibiting private slaughter-houses. The fees that could be charged at the municipal slaughter-house would more than cover the outlay. The Federal Government would on its side have to intervene by a general law to prevent the removal of the Chicago business to some other place where the local regulations might be less strict. Here, again, the necessity of a general law is felt. The municipality of Chicago may plead as its excuse for allowing such abominations to grow up in its midst that had it been more careful and stringent the business would have gone elsewhere to the detriment of the revenues and prosperity of the city. But there is something that is more important than revenue and that is public health. Only public health needs uniform laws, otherwise evils will grow up where the law least interferes. So the Chicago stockyard grievance must be dealt with from the national as well as from the local standpoint. An immense economic problem is involved; but it is a health problem as well, because health primarily depends on food—wholesome, clean food. Fortunately, there are some highly educated and public-spirited American men and women who realise the importance of this great problem and are grappling with it from various points of view. The President of the United States is not indifferent. It is said, on the contrary, that Mr. Roosevelt has determined to take in hand the question of the beef trust. There can be no better handle for dealing with this than the need to protect public health and in Europe there are many precedents to show how this has been done and done not only to the benefit of the public and of public health but also to the profit of the trade itself. In a word, the intervention of the State and the municipalities has proved, at least in this matter of slaughter-houses, to the lasting and real advantage of all concerned.

CHOLERA AND PLAGUE IN THE NEAR EAST.

(FROM THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

THE following has been the course of the cholera epidemic in Turkey and the adjoining countries since the date of my last letter, published in THE LANCET of Dec. 24th, 1904.

No case of the disease is believed to have occurred at Bagdad since Nov. 30th. At Basra a single case was observed on Dec. 1st and none has been reported since. At Amara there were two cases and three deaths between Dec. 2nd and 7th, and the epidemic is thought to be at an end there. At Suleimanieh 34 cases and 21 deaths occurred between Nov. 18th and Dec. 15th and between the same dates there were 40 cases and the same number of deaths at Mamouret-el-Hamidié. At Revendouz a more serious outbreak has occurred, 203 cases with 185 deaths being reported there between Nov. 30th and Dec. 10th, and 21 cases with 16 deaths between the 10th and the 13th. The disease has also appeared among the Abu-Abdullah division of the nomad tribe of Ascara, whose camps are at present in this vilayet between the *caza* of Souk and the *sandjak* of Muntefik, along the lower reaches of the Tigris; but no figures are forthcoming as to the intensity of this outbreak. At Rania 42 cases and 42 deaths were recorded before Dec. 14th and a week later it was reported that the disease was still present there and at Keui-Sanjak but was on the decline in both. At Deir-Zor there were 15 cases and 16 deaths between Nov. 30th and Dec. 12th. At Hay no case of cholera was recorded in December and towards the end of the month it was reported that the state of Kerbela and Nedjef—where severe measures of precaution are said to have been taken during the Bairam fêtes—was satisfactory as regards epidemic disease.

At the very end of December cholera appeared at Van in Turkish Armenia. Information is at present lacking to show whether the infection reached this district from Russian Transcaucasia in the north or from Mesopotamia in the south. On Dec. 30th and 31st 27 cases with 12 deaths were observed there; in the first seven days of January there were 79 cases with 46 deaths and between Jan. 8th and 13th 14 cases with 5 deaths.

Information as to the behaviour of cholera on Persian territory continues to be fragmentary. Writing on Nov. 3rd the Ottoman sanitary delegate at Tehran reported that cholera was raging with new intensity at Meshed-i-Sar on the Caspian Sea. It had also just appeared at Ardebil, where it was causing many deaths daily. The Tehran board of health, which has recently been showing sporadic activity, had proposed to establish observation posts on the principal roads from Tehran to the provinces of Azerbeijan and Mazanderan. It also proposed to stop all travellers at Astera, Enzeli, Mendjil, and Kazvin, and "to turn back the sick"; to prohibit all pilgrimage until the epidemic is over by refusing passports to intending pilgrims; to re-establish "with rigorous severity" medical inspections, and if necessary quarantine, on the Turco-Persian frontier; and to open at least two inspection posts one or two days' journey on the Persian side of that frontier where persons sick with cholera or suspected cholera would be put in hospital. It is not yet known whether these proposed measures have been really executed.

Another report from the same source, dated Nov. 9th, states that according to information given by the Customs authorities cholera was still raging at Meshed-i-Sar, where it was causing an enormous mortality so that "the whole region had become one huge cemetery." The physician to the Russian legation at Tehran had reported that around Resht and Enzeli the disease had caused "veritable hecatombs" and there was general panic. It was also prevalent at Kerman and Kazerun; it had broken out with renewed severity at Maragha; it was lessening at Ispahan; and was also diminishing at Tabriz—after causing there a mortality of between 12,000 and 18,000. The disease was still present at Sarakhs, Navrouzabad, Singar, and Devlet. At Saoutch-Boulak there was a panic with flight of the population. Only sporadic cases were occurring at Miandjié and Khosrovabad but there was a revival of the epidemic at Nehi-abad and in the plains of Khaf.

In a third report, dated Nov. 16th, it was stated that cholera was very intense at Mohamerat (? Mohamerah on the Shatt-el-Arab); that the epidemic was over at Tabriz; but that the disease was still epidemic at Ardebil. In a fourth report, dated Nov. 19th, it was stated that there was a revival of the outbreak at Kazvin and in the Mazanderan province. Finally, in the fifth report, dated Nov. 23rd, the same authority asserts that a regiment of recruits marching from Tabriz to Tehran had been attacked by cholera and had sown the infection broadcast along the course of their march. They were then encamped outside Tehran, and no precautions being taken to prevent their communicating with the town one case of cholera had already occurred in an inhabitant of Tehran near the site of their camp. The Customs authorities reported that a grave form of cholera was prevalent at Mohamerah where most of the cases ended in death. A new explosion of the disease had occurred at Kazvin and at Yengué-Imam owing to the passage through these places of the above-named regiment of recruits. At Tabriz also there had been a recrudescence, and there were still sporadic cases throughout the whole province of Ghilan. In the province of Ghoutchan (*sic*) cholera had appeared in the village of Ali-abad and was spreading southwards. The disease had revived at Kelate and Gharatikan; it was causing 8 deaths daily at Kerganeroud, 20 deaths daily at Astera, and was raging, with consequent flight of the population, at Chefa-Roud and Taleh. (I give the names of these places as they are spelt in the report from which they are quoted. Most of them cannot be identified on the maps at my disposal.) Many deaths were still occurring at Saoutch-Boulak; at Kerman 15 deaths were being daily recorded, and at Kashan the epidemic was at its height.

To the above notes may be added the statement that in Tehran a considerable mortality has recently been observed from diarrhœa, dysentery, and typhoid fever, all of which diseases have been traced to contaminated water-supplies; that a grave form of typhoid fever was epidemic at Kerman, and that "typhus" (though whether this means petechial or abdominal typhus is not clear) was prevalent at Maragha and at Meshed-i-Sar.

The following figures relating to the prevalence of cholera on Russian territory are given on the authority of the official announcements in the Russian journals. There has been an increase in the outbreak, followed by a decline, in the military post of Serakhs in Transcaspia. Between Nov. 16th and 21st there were 25 cases here with 13 deaths; between the 23rd and 29th there were 27 cases and 20 deaths; between Nov. 31st and Dec. 6th, 4 cases; between Dec. 7th and 14th, 4 cases, and apparently none since. On Nov. 24th cholera appeared in Tashkent and its neighbourhood, where 18 cases were recorded on the 24th and 25th and 4 more cases in the four following days. Between Nov. 31st and Dec. 6th there were 16 cases here with 7 deaths; between the 7th and 14th, 11 cases in the town and 22 cases with 16 deaths in the district of Tashkent; and between the 15th and 21st 4 cases in the town and 28 cases in the district. Between Dec. 7th and 14th the disease appeared in Askhabad and caused 3 cases, followed by 5 other cases in the subsequent week. One case has also occurred at Krasnovodsk, imported from Tashkent. Cholera is still present in Baku, where it caused 27 cases and 8 deaths in the week ending Nov. 22nd, while in the same week there were 13 cases in the Baku district, 22 in the Lenkoran district, and 2 cases in that of Djevat—all in the Baku government. In the week ending Nov. 29th there were 53 cases in Baku and the Baku government, and in the following week 66 cases in the town itself and at Balakhani in its neighbourhood. In the Lenkoran district of this government there were no less than 376 cases with 331 deaths between Nov. 21st and Dec. 3rd, and 177 cases with 152 deaths between Dec. 7th and 14th. In the Djevat district there were 286 cases and 217 deaths from the beginning of the epidemic on Nov. 4th to Dec. 3rd, and 264 cases with 203 deaths between Dec. 7th and 14th. In the Kubin district there were 20 cases and 14 deaths between Nov. 21st and 29th. Finally, in six infected districts of the Baku government there were 168 cases between Dec. 15th and 21st and 10 cases in Baku itself in the same period.

In Tiflis 3 cases of cholera were observed on Nov. 19th; followed by 4 cases between the 23rd and 29th; 2 cases between Nov. 31st and Dec. 7th, and apparently none since. The following have been the figures received from the [illegible] ases in the Zangezur district [illegible] 32 cases between the 22nd and [illegible] 31st and Dec. 7th (including 1 case in a prisoner in the Elisavetpol town prison, and the rest in the districts of Zangezur, Djebrail, and Elisavetpol); 129 cases between Dec. 7th and 14th, and 9 cases with 5 deaths between the 15th and 21st. The outbreak in the Erivan government has been a particularly severe one. Between Nov. 16th and 22nd there were 522 cases and 342 deaths here, followed by 915 cases between the 23rd and 29th; 1018 cases and 661 deaths between Nov. 31st and Dec. 6th; 1352 cases and 1107 deaths between the 7th and 14th (including 956 cases and 839 deaths in the Erivan district, 241 cases with 177 deaths in that of Nahitchevan, and 154 cases with 158 deaths in the town of Erivan); and 324 cases with 279 deaths between the 15th and 21st (including 31 cases in the town of Erivan).

The following figures are from the Volga governments. In the town of Astrakhan there were 3 cases with 1 death between Nov. 16th and 22nd, and in the government of that name 11 cases and 5 deaths in the same period. Then between Nov. 23rd and 29th there were 6 fresh cases in the government; between Nov. 31st and Dec. 6th 6 more cases; between the 7th and 14th 1 case only (in Astrakhan itself); and between the 15th and 21st 3 cases. In the Saratof government there were 36 cases between Nov. 16th and 22nd; 40 cases with 19 deaths between the 23rd and 29th; 22 cases (of which 21 were in Tsaritsyn and one in the Volsk district) between Nov. 31st and Dec. 6th; 10 cases between Dec. 7th and 14th (all in Tsaritsyn); and 11 cases (in the same town) between the 15th and 21st. In the Samara government there were 13 cases between Nov. 16th and 22nd; 165 cases (of which 162 occurred in the Nikolaief district) between the 22nd and 29th; 32 cases between Nov. 31st and Dec. 6th; 17 cases between the 7th and 14th; and 70 between the 15th and 21st.

An outbreak of plague of some severity has recently occurred at Aden. Between Oct. 26th and Dec. 27th there were 203 cases with 144 deaths there. Of these, 182 cases and 131 deaths occurred in the crater which is five miles distant from the port; 18 cases and 10 deaths at Sheikh Othman, ten miles distant from Aden; 2 cases and 2 deaths at Malla, three miles from Steamer Point; and only 1 suspicious case at Steamer Point itself.

A remarkable outbreak of pueumonic plague is also reported from the Ural districts of Southern Russia and is said to have caused 190 deaths. Fuller details of this epidemic will probably be received later.

Constantinople, Jan. 17th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Specialism in the Indian Medical Service.

WITH the view of encouraging officers of the Indian Medical Service to qualify in chemistry the Government of India notifies that in selecting a probationer for the Chemical Examiner's Department preference shall *cæteris paribus* be given to an officer who has passed the intermediate or final examination of the Institute of Chemistry of Great Britain and Ireland or any equivalent examination, and that for appointment as chemical examiner preference shall *cæteris paribus* be given to a probationer who is in possession of the diploma of Fellow or Associate of the Institute of Chemistry or any equivalent degree or diploma. Other forms of specialism are to be encouraged particularly for sanitary appointments and for asylum work.

The Rapid Increase in the Mortality from Plague.

The rise in the mortality from plague throughout India continues and in some districts is assuming alarming proportions. There were 19,465 deaths for the week ending Dec. 24th, 1904, as compared with 18,284 for the previous seven days. The principal increases are in the United Provinces and the Punjab. In the former provinces the increase of late has been very rapid and 6822 deaths were recorded. No less than 41 out of 48 districts are affected and nearly all the chief towns. Cawnpore returns 295 deaths, Bareilly 186, and Allahabad, Aligarh, Lucknow, and Mirzapur return over 100 deaths each. The outlook for those cities which have been previously attacked is very serious. In Bengal the disease is also rapidly spreading, especially in some of the up-country towns. Both Bombay city and Calcutta show signs of a further recrudescence. The detailed figures published are: Bombay Presidency, 4154 deaths; Bombay city, 110; Karachi, four; Madras Presidency, 353;

Calcutta, 18; Bengal, 2005; United Provinces, 6822; Punjab, 3940; Central Provinces, 359; Mysore State, 39; Hyderabad, 809; Central India, 132; Rajputana, 345; and Kashmir, eight. It must be borne in mind that these figures of weekly mortality are only approximate as registration is everywhere very defective. It is possible that the true mortality from plague is 50 per cent. over the published figures.

The Septic Tanks on the River Hooghly.

The outcry made by the Hindu community some months ago against the drainage of the septic tanks connected with several mills on the river Hooghly above Calcutta led to the appointment of a committee of inquiry. Its report has just been published. It was found that the effluents varied in purity but for the most part contained no perceptible solids and were non-putrescible. Chemical analysis showed, however, that the results compared unfavourably with reports of similar analyses made in England. The nitrates were in insufficient amount while the albuminoid ammonia was in excess. Bacterial analysis also showed a large number of colon bacilli and a general bacterial contamination. The amount of river water with which the effluents became diluted was not capable of any trustworthy estimate. The committee considers that these septic tanks are a vast improvement on the old system of latrines and that a stoppage of the use of the tanks would probably increase the pollution. It suggests certain methods of improving the effluents. The great danger is in the dry season when the river flow is small and it concludes that the effluents in their present condition should not be emptied into the river above the waterworks or near them. The objections of the Hindu community are on religious grounds by some members and on sentimental grounds by others. As it is impracticable to pass the effluents over land it is suggested that, failing improvement in character, the fluid might be used as feed water for boilers; but here, again, difficulties may arise from the workmen. There is little doubt that these septic tanks can be improved in construction and use but the objections against them are, I think, fanciful in the circumstances present here. It is forgotten how much the river is polluted by the inhabitants living on the banks and by the thousands who go down to bathe and considering the size of the river the objection against the septic tank effluents from a few mills is simply a vexatious one and probably arises from an ignorance of the process by which the sewage is purified in these tanks.

Jan. 7th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

University Intelligence.

SINCE my last letter Mr. H. Gilbert Barling has been appointed by the Council of the University dean of the medical faculty. Mr. Barling, who came to Birmingham nearly 25 years ago, is professor of surgery, honorary surgeon to the Birmingham General Hospital, and a member of the Council of the Royal College of Surgeons of England. Since the inception of the University he has been vice-dean of the faculty. He has made many valuable contributions to surgical literature. His lectures upon appendicitis delivered at the University under the Ingleby trust were at the time, and have remained since, one of the most authoritative works upon the subject. The University is to be congratulated upon its good fortune in being able to induce Mr. Barling to spare from his other work the time requisite for the office, the successful tenure of which is felt to be insured by all those who are acquainted with his business ability and tact. The principal's report for the years 1904–05 contains a reference to the Dental Hospital. For some time past the students in dentistry have suffered from the undoubted inconveniences inseparable from so antiquated a building as the old Dental Hospital. All interested in the school will be glad to hear that such disabilities are to be speedily removed by the opening of a new hospital possessed of all modern requirements. It is estimated that the building will cost £10,000, of which more than half has already been raised. The principal in his report took the opportunity of saying how closely allied the medical and the dental faculties were in their fortunes and that he hoped a special effort would be made to open the building free of debt. He said that as the only school in the country at present privileged to grant a degree in dentistry it was incumbent upon the university authorities to see that the preparation for their degrees was of as thorough and scientific a nature as possible.

The Health Committee.

The question of the milk-supply in Birmingham has occupied of late the attention of the health committee and in this connexion a circular letter has been addressed by the medical officer of health to the farmers of the district pointing out the ways in which contamination occurs and the rapidity of the multiplication of germs in milk. To prevent these mischievous results the farmers are requested to see that more regard is paid to cleanliness by the milkers and that the milk is stored under such conditions that its temperature will not be higher than 45° F. A long report on the method by which "humanised" milk is distributed in Liverpool was presented by a deputation of the health committee which had recently visited that city for the purpose. It is believed that some such scheme will be adopted in Birmingham. At the same meeting the question of the advisability of framing regulations for hairdressers' and barbers' establishments was also considered. The matter was referred to the medical officer of health for his consideration.

Birmingham, Tame, and Rea Drainage Board.

At the last meeting of the above board the members were strongly advised by their engineer, Mr. J. D. Watson, to substitute as opportunity arose bacteria beds for the intermittent filters now in use at their farm. He supported his recommendation by stating that 15 acres of bacteria beds were capable of dealing with the sewage for which at present 1000 acres of intermittent filtration beds are required, that this would set free a great area for growing grass and roots, and that the effluent from bacteria beds is purer than that from filtration beds.

The Health of the City.

The death-rate in Birmingham for the week ending Jan. 14th was 19·8 per 1000, as compared with 21 per 1000 in the previous week; the zymotic death-rates in the same periods were 1·0 and 0·7. The number of patients in the scarlet fever hospital and in the typhoid fever wards was in each case reduced, the gratifying report being made that there was now no pressure on the accommodation in the isolation hospitals. The slight rise in the zymotic death-rate was due to deaths from whooping-cough and pulmonary tuberculosis. Influenza has been accountable for a large amount of sickness in the city and in the surrounding Black Country.

The Floodgate-street Area

At a meeting of the Birmingham magistrates held on Jan. 19th to consider a report of the licensing committee upon the Licensing Act, 1904, it was possible to obtain some information as to the probable attitude to be adopted by the committee towards the Floodgate-street area. Mr. Chance, the chairman of the committee, said he believed there were some who thought that considering the report of the medical officer of health the magistrates should confine their attention to this area. He did not think so; he pointed out that of the houses scheduled in this area more than half were fully licensed houses, many of which it would be very expensive to close. He considered that more good would be done to Birmingham if the committee was not restricted to this area and if it was allowed a little latitude to go outside. A motion, however, that the attention of the committee should be first drawn to the number of superfluous licensed houses in this area was carried.

Jan. 24th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Princess Christian at the Liverpool School of Tropical Medicine: Major Ronald Ross's Lecture on the Progress of Tropical Medicine.

Her Royal Highness Princess Christian visited Liverpool on Jan. 12th to attend a lecture by Major Ronald Ross, C.B., F.R.S., late I.M.S., on the Progress of Tropical Medicine and on some phases of the work of the Liverpool School of Tropical Medicine. Her Royal Highness was accompanied by the Princess Victoria of Schleswig-Holstein, the Earl and Countess of Derby, and the Right Hon. Joseph Chamberlain, M.P., and Mrs. Chamberlain. Sir Alfred Jones, K.C.M.G., who presided, explained to Her Royal Highness that

Liverpool was doing what it could to push forward the study of tropical medicine which was for the common good. The tropics had already been made more habitable for the British people. The people of Liverpool had enabled them to spend £50,000 on the work but nothing would have been done but for the example of Mr. Chamberlain and the thanks of the school were due to him. Major Ross in the course of his lecture remarked that disease was the principal bar to progress in tropical countries. Particularly in the case of tropical Africa one was struck with the fact that that great continent still remained uncivilised in spite of its proximity. There was only one way to grapple with the great enemies of civilisation: they must sit down patiently with the microscope and the test-tube. Having dealt with the vague medical knowledge of tropical maladies up to a recent time he said that perhaps the earliest light came from a study which was despised by many—namely, that of the parasites of man and of animals. Tracing the progress of the study he referred particularly to the discovery that the malaria germ was carried from the marshes to human beings by mosquitoes. It was often asked whether malarial fever could not be produced in other ways than by the bite of mosquitoes. He could only say that no satisfactory evidence of this had yet been given and, moreover, that for zoological reasons it was exceedingly unlikely that the parasite, which already possessed a sufficiently complex life-history, could exist in other localities besides its own proper hosts, man and mosquito. The fact that yellow fever was carried by mosquitoes only was now determined with the utmost certainty. The germ had not yet been found but the manner in which it attacked was known. During the last quarter of a century pure science had made discoveries which had resulted in the partial or complete solution of the problems in connexion with five or six tropical diseases but it did not follow that life would be benefited. Neither the general public nor scientific men seemed fully to realise this point. If to-morrow he were to discover a method of checking any disease, so simple that it could be applied without the smallest difficulty, were they convinced that it would be so applied the day after to-morrow? He knew that it would probably not be applied for years or perhaps even for centuries. That seemed a bitter thing to say and some might doubt whether it was true but he would give a case where it had actually happened—he meant the case of vaccination against small-pox. When, therefore, the mode of propagation of malaria was discovered it became obvious that a great propagandism must be carried out. The public must be informed of the new discoveries and the State must be requested to take action. They owed the initiative in that matter to Mr. Chamberlain who, early in 1899, publicly formulated a scheme for the creation of schools of tropical medicine—that was to say, he at once recognised the public importance of tropical medicine and at the same time did his utmost to encourage the further study of it. The Liverpool School, ably led by Sir Alfred Jones, had collected funds for a large amount of pure scientific work, also for direct sanitary labour; and the London School and the schools of Hamburg and elsewhere had contributed their share. A few months after the Liverpool School was established it sent out an expedition to Sierra Leone which discovered the species of malaria-bearing mosquitoes there existing and showed exactly how to deal with the disease in large towns. It sent other expeditions to the Gambia, to the Gold Coast, to Lagos, and to the Congo. These had mapped out the health conditions of the coast in a manner which was never attempted before. They had sent out no less than 14 of such expeditions to various parts of the world and had published 12 separate works and reports on the subject. He explained what the anti-mosquito crusade accomplished, resulting in improvement of health in some districts and in the [illegible] yellow fever from Havana. [illegible] fever fell within one year f[illegible] of malarial, yellow fever, elephantiasis, and other germs in various phases of development were then given on a screen and explained by Major Ross. A vote of thanks to the lecturer was proposed by Mr. Chamberlain which was cordially carried.

Return of Professor Rubert Boyce from West Africa: the Health of West Africa.

Professor R. Boyce, [illegible] out recently from Li[illegible] on a special expeditic[illegible] of Tropical Medicine, returned to Liverpool on Jan. 22nd. It is understood that valuable knowledge has been acquired which will be embodied in a report. Professor Boyce states that, although the West Coast of Africa will not become a health resort some parts in certain seasons may become quite healthy. The health of Europeans in many of the coast towns now shows a marked improvement and will no doubt continue to improve. This is attributed to increased sanitation, including anti-mosquito measures, new residences in selected quarters, and more careful selection of those who go out and who in consequence realise how to live in a tropical climate and to avoid infection from malaria and other diseases.

Opening of the James Hakes Memorial Hall.

At the annual meeting of the Liverpool Medical Missionary Society held on Jan. 23rd the ceremony of opening the new dispensary building and James Hakes Memorial Hall took place. Miss Hakes declared the buildings open and addresses were delivered by Dr. William Carter, J.P., and Dr. Bond, the medical officer to the society. The late Mr. James Hakes, who was surgeon to the Liverpool Royal Infirmary, was one of the founders and most liberal supporters of the mission and Miss Hakes made the generous gift of £1000 to build the new hall in memory of her father. The whole cost amounted to £3900. There are consulting and dispensary rooms and accommodation for nurses and others in the medical division of the buildings.

Hospital Extension at Ormskirk.

A meeting of the Ormskirk and Lathom joint hospital board was held on Jan. 18th, at which it was resolved that the scheme of extension of the hospital and alteration of the administrative block should be proceeded with in accordance with plans submitted; and that application should be made to the Local Government Board for borrowing powers. It is estimated that the work will involve an expenditure of about £3000. A letter was read from the Earl of Derby's agent intimating that his lordship was willing to sell to the board for the purposes mentioned 5254 square yards of land in Green-lane, Ormskirk, at 2*s.* per square yard. It was resolved that the offer should be accepted and a provisional agreement entered into.

Jan. 24th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

University of Leeds.

Dr. C. M. Chadwick, who has held the professorship of materia medica and therapeutics since 1898, has tendered his resignation and the Council referred the question of the "teaching and manner of dealing with the chair, which includes the subjects of materia medica, practical pharmacy, pharmacology, and therapeutics," to the Board of the Faculty of Medicine. The following report of the board on this subject was approved by the Senate and adopted by the Council:—

[illegible]

on such terms and conditions as [illegible] this report to be carried into effec[illegible] [illegible] acology of the [illegible]

Jan. 24th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Employment of Tramps in Glamorgan.

REPRESENTATIVES from each of the eight boards of guardians in Glamorgan and from several of the sanitary [illegible] on Jan. 21st [illegible] labour farm [illegible] Mr. Joseph [illegible]

Fels offered to purchase land in any part of the county suggested by responsible local authorities and to let it to them at a peppercorn rent for three years; at the end of this period the land could be given up altogether to Mr. Fels or purchased from him at the price that he gave for it. A suggestion was made that 100 acres should in the first instance be purchased on the terms offered and managed by a joint committee of the local authorities. Employment for 100 men would thus be obtained and it was estimated that the cost of the undertaking would not entail an annual expenditure equal to a farthing rate over the whole county. No definite conclusion was arrived at with regard to the offer of Mr. Fels but it was decided to report the details of the proposal to the several authorities who were represented at the conference. A deputation consisting of Welsh Members of Parliament and others was appointed to bring under the notice of the Government a resolution unanimously adopted to the effect that the problem of the unemployed being national in its scope could only be effectually dealt with by the State and that the Government be therefore called upon to deal with the question without delay.

Bath Small-pox Hospital.

The provision of a small-pox hospital has for several years been under consideration by the corporation of Bath, the only accommodation at present existing for the isolation of cases of the disease being in the iron buildings which are used also for the isolation and treatment of other infectious diseases. Great difficulty has been experienced in obtaining a suitable site for the hospital but during last year ground was acquired outside the city boundary and plans were drawn for a well-equipped institution to be built of Bath stone. The proposed buildings included a small administrative block and a pavilion with two six-bed wards and two one-bed observation wards. The cost was estimated at £3750. At the meeting of the corporation held on Jan. 17th the sanitary committee recommended the carrying out of the work above indicated but so great was the opposition to the scheme from the residents in the neighbourhood of the proposed site that it was decided to ask the committee to reconsider the whole question. The principal argument of the opponents of the scheme appears to have been that a portion of the site, though not of the actual hospital buildings, would be within half a mile of the union workhouse.

The Sale of Food and Drugs Acts in Bristol.

In the administration of the Sale of Food and Drugs Acts in Bristol during 1904 the samples of food submitted for analysis numbered 735 and 52 of these were condemned by the public analyst. Of milk 278 samples were taken and 30, or 10·8 per cent., were found to be adulterated. It is satisfactory to find that this percentage is lower than that of 1903, when it was 13·9. At a recent meeting of the corporation the inspector under the Sale of Food and Drugs Acts was appointed to administer the Shop Hours Closing Acts and his salary was raised from £200 per annum to £300. He was also given an assistant at a salary of £130 per annum. At the same meeting of the city corporation the sanitary committee recommended an increase in the salaries of the five district surveyors who now receive from £220 to £240 per annum and also advised the appointment of an additional surveyor in view of the recent extension of the city boundaries. These recommendations were strongly opposed and in the end successfully. The duties of an inspector under the Sale of Food and Drugs Acts are unquestionably responsible and require the exercise of tact and firmness but it is a little difficult to understand why they should be esteemed of more value than those of trained sanitary officers whose want of skill might do incalculable harm.

Bristol Dispensary.

The Bristol Dispensary was established so long ago as 1775 for the relief of the sick poor at their own homes but many patients are now treated either at the institution on Castle-green or at the branch at Bedminster. During 1904 the number of persons under treatment was 10,556, a slight decrease upon the previous year. The finances of the dispensary appear to be satisfactory, there being a balance in hand of £10, although on the year's working there was a loss of £15.

Clutton Workhouse.

At a recent meeting of the Clutton (Somerset) board of guardians, which represents a population of 25,000 persons, Mr. Preston Thomas, Poor-law inspector of the Local Government Board, animadverted upon the accommodation for tramps in the workhouse, more especially as regards the sleeping accommodation and the absence of a bath and means for disinfecting clothes. At present in wet weather the want of proper shelter prevents the tramps carrying out their allotted work and Mr. Thomas urged that such arrangements should be made that it would be possible for each man to do a day's work in return for his board and lodging. At the next meeting of the board of guardians the question of erecting new tramp wards will be considered.

Vagrancy in Wiltshire.

The chief constable of Wiltshire has reported to the county vagrancy committee that during last year 36,991 tramps were relieved, compared with 28,553 in 1903. The increase was very noticeable in the last quarter, the number in each year being respectively 11,479 and 7859. A midday meal was provided for 14,405 persons in 1904 at a cost of £57 while in 1903 there were fed 11,430 at a cost of £44.

Merthyr Education Committee.

Mr. D. J. Thomas, medical officer of health of Merthyr Tydvil, has been appointed medical officer to the education committee at an annual salary of £30. Among his other duties he will be required to visit, when instructed by the committee to do so, any teachers who are frequently absent from duty on account of alleged illness and to report to the committee upon the circumstances of the case.

Horfield Inebriate Reformatory.

The Home Secretary has granted a new certificate to the Horfield Inebriate Reformatory, in the county of Gloucester. The number of females to be detained is not to exceed 20. The reformatory is reserved for the better class of inebriates committed under the Inebriates Act, 1898, and no inmate is to be admitted except by transfer from another reformatory.

Jan. 24th.

SCOTLAND.

(From our own Correspondents.)

The Western Infirmary, Glasgow.

The new dispensary in connexion with the Western Infirmary, Glasgow, was formally opened on Jan. 18th by Lady Blythswood. Sir Matthew Arthur, chairman of the managers, presided, and among those present were Lord and Lady Blythswood, Sir John and Lady Primrose, Sir Lauder Brunton, Sir Hector Cameron, Principal Story, Mr. Henry E. Clark (President of the Faculty of Physicians and Surgeons), Professor McCall Anderson, Dr. J. Finlayson, Dr. Donald Macleod, Dr. D. J. Mackintosh, and Mr. Henry Johnston. The chairman, in giving an outline of the progress of the work, said that a public appeal for the necessary funds to erect a new dispensary was made in 1897 and resulted in the raising of about £24,800. Estimates were accepted in 1902 and building operations were commenced but the cost of the building had exceeded the amount subscribed by £10,000. Besides the relief it afforded to the sick poor a dispensary such as that was an important adjunct to medical education because it was compulsory for students to attend the out-door practice of a hospital, and here there were on an average about 400 students enrolled. In the design of the buildings attention had therefore been given to the provision of increased facilities for teaching and to extending the opportunities for scientific study. The architect was Mr. John James Burnet and the managers were much indebted to Dr. Mackintosh for the careful attention that he had given to the details which would greatly facilitate the working. After Lady Blythswood had declared the building open the chairman, on behalf of the contractors, presented her with a silver bowl as a memento of the ceremony and Lord Blythswood in a short speech returned thanks for his wife. Sir Lauder Brunton then delivered a brief address, dealing chiefly with the benefit of dispensaries to the community at large, the great necessity for a pure milk-supply, and the establishment of a national league for physical education and improvement. Such a league, he said, was in process of formation and would strengthen existing organisations having similar objects. The proceedings then terminated with votes of thanks to Lady Blythswood, Sir Lauder Brunton, and Sir Matthew Arthur.

Death of Brigade-Surgeon Alexander Johnston.

The death occurred on Jan. 18th at Ryde, Isle of Wight, of

Dr. Alexander Johnston, brigade surgeon, in his sixty-fourth year. Dr. Johnston was a native of Aberdeen and studied medicine at Marischal College, where he graduated as M.D. in 1864. His ambition lay in the direction of the Army Medical Service and he was successful in receiving an appointment to join the forces on the West Coast of Africa where the rest of his life was chiefly spent, Lagos, Cape Coast Castle, and the other stations being visited in the course of his term of office. He retired on a pension several years ago and afterwards took up residence at Queen's-road, Aberdeen, but on the death of his wife he went to live in the Isle of Wight on account of the state of his health. Dr. Johnston had no family. He was of a retiring disposition and took no part in public affairs but was highly esteemed in the profession and by all with whom he was associated.

County Hospital Dispute.

Sheriff Lee has just decided a somewhat important action which was raised in Arbroath Sheriff Court at the instance of the Dundee and Forfar district committees of Forfar county council against the Arbroath district committee for payment of £274 for the maintenance of patients sent from the Arbroath district of the county to the pursuers' joint hospital at Forfar during the year ending Whitsunday, 1904. The sum sued for included a proportion of the permanent charges of building and maintaining hospital and staff and the defenders pleaded that they were liable only for payment of a rate per patient. The pursuers' account showed that the rate was 30*s.* per week and the defenders tendered an offer of £49 10*s.* in full, [illegible] weeks. Sheriff Lee [illegible] effect to the defende [illegible] in expenses. He ho [illegible] put on the pursuers' [illegible] defenders were liable only for payment of a certain rate per patient and he found no warrant or authority in that letter for charging the defenders with a proportion of the permanent charges of the hospital. In a note to his interlocutor the sheriff characterised the contract which the pursuers alleged had been entered into as a gambling contract and said that no public body was entitled to enter such.

Jan. 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Public Health of Dublin.

AT the last me [illegible] which was held in the [illegible] Charles Cameron reporte [illegible] ending Dec. 31st, 1904, was 3 per 1000 below the mean rate, while the zymotic death-rate was 2 per 1000 above the mean, being raised by an outbreak of measles which during the last five weeks had caused 50 deaths. The epidemic was almost altogether confined to the south side of the city, only one case having occurred on the north side. In other words, while no less than 50 deaths took place on the south side of the river, only one case was notified on its northern side.

Death of Professor Ambrose Birmingham, M.D. R.U.I., F.R.C.S. Irel.

Professor Ambrose Birmingham, one of the best known and most highly esteemed of the medical teachers of Dublin, died on the night of Jan. 23rd at the early age of 41 years. After a most distinguished career as an undergraduate of the Royal University of Ireland he became demonstrator, and afterwards professor, of anatomy at the medical school of the Roman Catholic University. He was a highly successful lecturer and by his talents and energy soon doubled the number of students seeking education at the medical school.

The Milk Question in the North of Ireland.

If the public of the North of Ireland are not initiated into the mysteries of "the milk question" it will not be the fault of the Belfast local papers in which we are being treated almost every day to lectures, letters, and articles on this subject. The discussion began a short time ago when a public lecture was delivered in which sterilised milk was strongly recommended for infants under one year old, as well as for adults who were weak or who were suffering from diarrhœa, consumption, and wasting diseases; and it was also urged that sterilised milk was required as a food for those attacked with infectious or zymotic fevers. This teaching has raised a storm of opposition on the part of those who contend that sterilised milk—as has been demonstrated both by scientific investigation and by clinical experience—is not merely objectionable but is often positively dangerous to children owing to its diminished nutritive value. Those who object to sterilised milk say that what is needed is not a method of treating milk like sterilisation which simply palliates effects, does no real good, puts a premium on carelessness and uncleanliness, and tends to retard progress in the right direction; what is wanted, they say, is a really pure clean milk which is "dairied" and distributed in such a way that the consumer receives the milk just in the same condition as it left the cow. It is hoped that some good will come out of this discussion and that the health authorities of Belfast will try to keep pace with the teaching of clinical experience and of scientific experiments and will really put in force the laws, so that we may have clean dairying and hygienic distribution of milk. It is very much to be regretted that the Belfast public health committee so rarely takes the initiative in any public health reform, only moving when compelled to do so by the force of outisde public opinion.

Death of Dr. O. M. Praeger.

Dr. O. M. Praeger, resident surgeon in the fever department of the Belfast union workhouse, died on Jan. 16th. He was 31 years of age. A member of an old and distinguished Belfast family, Dr. Praeger was educated at Queen's College, Belfast, and graduated in 1900 in the Royal University of Ireland. He was a popular student and took an active share in 1904 in the bazaar for the Students' Union and when the Students' Union was opened he was president of it and he was first editor of the college magazine, "*Q.C.B.*" After graduating he was appointed on the resident staff of the Belfast workhouse and for four months last year he was resident officer of the Purdysburn Small-pox Hospital. At the usual meeting of the Belfast board of guardians held on Jan. 17th the very greatest surprise and regret were expressed by the chairman and all the guardians at the sad news of Dr. Praeger's sudden death and throughout Belfast the very deepest sympathy is felt for his mother and for his sorrowing relatives.

Ulster Medical Society.

A meeting of the Ulster Medical Society was held in the Medical Institute, Belfast, on Jan. 19th, Dr W. Calwell, the President, being in the chair. Mr. A. B. Mitchell showed a patient, the subject of Œsophageal Stricture, with a Symond's tube which he had worn for six months, and a case operated on for Hare-lip and Cleft Palate. Dr. W. B. McQuitty read notes of a case of General Paralysis. Dr. H. L. McKisack read a paper on the Treatment of Pneumonia by the External Application of Ice, and Dr. J. C. Rankin read a paper on X Ray Treatment and showed several cases of rodent ulcer, lupus, &c., treated by this method. In the discussion which followed the reading of these papers, Professor J. A. Lindsay, Dr A. Dempsey, Mr. Mitchell, and the President took part.

Coronership for Belfast.

For the coronership of Belfast, vacant through the death of Mr. E S Finnegan (solicitor), Dr. James Graham (late chairman of the public health committee) and Mr. John Finnegan (son of the late coroner) are candidates.

A Medical High Sheriff for Belfast.

Dr. Henry O'Neill has been nominated as High Sheriff for Belfast by the city corporation, of which he is a member. He is the first medical man to attain this distinction in Belfast.

Medical Practice in the Canton of Zurich.

THE various "physical health societies" in the canton of Zurich have a membership of several thousand persons and they have been trying to bring in a law sanctioning "free medical practice" in the canton. The effect of such an enactment would be to encourage quack practitioners of every sort. Among the 24 cantons in Switzerland there are only two (Glarus and Appenzell) in which "free practice" is permitted. The medical men of the canton did all they could to prevent measures so disastrous to the health of the population, especially as regards infective cases, being introduced. The question was thoroughly discussed in dozens of daily and weekly newspapers and in many meetings convened for the purpose; many thousands of Dr. Alexander's pamphlet on the disastrous results of "free medical practice" in Germany were also distributed. These discussions have had the effect of counteracting the hostility of the "physical health societies" to pharmaceutical and therapeutical science. On Nov. 30th, 1904, the question put to the public vote was carried against "free medical practice" by 51,000 votes against 22,000. Meanwhile the official authorities have consented that a professor should be appointed at the University to lecture on physical and dietetic therapeutics; this also is in conformity with the views of the medical profession at large, as it is desirable that public opinion should be able to recognise the errors of the statements made by the "physical health societies." The Cantonal Medical Society of Zürich at its last meeting appointed a committee composed of two professors, members of the medical faculty of the University at Zürich, and five medical practitioners to consider this question and to submit a report to the authorities.

Treatment of Infantile Broncho-pneumonia.

Dr. Theodore Zangger of Zürich has published in the *Correspondenzblatt für Schweizer Aerzte* of Jan. 1st an article on the Treatment of Infantile Broncho-pneumonia. This disease is responsible for one-twelfth of all the deaths in Switzerland, nearly 5000 children succumbing to it every year. As regards the mortality of this malady there are very few recent statistics based on a large number of cases. Bartels, von Ziemssen, and Steffen report a mortality of 41 per cent. in 231 cases. Roger finds a mortality of 75 per cent. in pneumonia complicating whooping-cough and Comby the even more appalling mortality of 81 per cent. in 715 cases of pneumonia after measles. Dr. Zangger has carefully examined the trustworthy statistics of the town of Zürich. Both the Children's Hospital (98 cases) and the out-patient department of the University (802 cases) report only 20 per cent. of deaths. 146 of these cases refer to pneumonia after measles, 108 to pneumonia after whooping-cough, and 476 to simple broncho-pneumonia. Dr. Zangger believes that proper bath treatment, the details of which he published in THE LANCET of June 28th, 1902, p. 1826, will further diminish this mortality. He describes at length ten cases thus treated, in all of which the inflammatory process subsided within eight days, generally after the employment of from two to eight baths. When it is considered that the mortality of whooping-cough and measles almost entirely depends on the favourable or unfavourable issue of a complicating pneumonia, this treatment of infantile pneumonia, which need not supersede medicinal treatment, deserves the serious attention of the profession.

Zurich, Jan. 23rd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Variola Hybrida (So-called).

Dr. Happel read before the American Medical Association in 1901 a paper in which he described a species of small-pox as variola hybrida and he further gave it as his opinion that the epidemic then prevailing widely in the United States was for the most part not genuine small-pox but a sub-species. Dr. A. H. Mansfelde of Ashland, Nebraska, read before the Nebraska State Medical Association at a meeting held last May at Omaha, Nebraska, a paper in which he upheld the views of Dr. Happel. Dr. Happel defines variola hybrida as a modification of small-pox in which not the person but the virus which produces the disease has undergone a vital change and he states that the two modifications of small-pox, varioloid and variola hybrida, are nowhere to be taken as convertible varieties of genuine small-pox. Dr. Mansfelde believes variola hybrida to be a species of small-pox but that is far from the disease being entitled to be called genuine small-pox. He thinks that it is a hybrid form of the classical disease, hybridised in its seed, whether that be of vegetable or of animal origin. The views of Dr. Happel and Dr. Mansfelde have received little support in the United States, the great majority of the medical profession regarding the epidemic as one of genuine small-pox.

Medical News.

UNIVERSITY OF CAMBRIDGE.—Mr. Ivor L. Tuckett, Trinity, has been appointed an additional demonstrator of physiology.—The following candidates have passed the examination in Tropical Medicine and Hygiene and are entitled to the University diploma:—

D. H. Ainslie, D. Alexander, C. A. Bentley, J. M. Buist, J. H. Cook, T. G. D. Cooper, J. W. Cornwall, W. A. Densham, and C. E. Williams.

There were 15 candidates.—The following degrees were conferred on Jan. 19th:—

Doctor of Medicine.—R. H. Marten, Caius.
Bachelor of Medicine.—F. L. Woods, Caius.
Bachelor of Surgery.—G. F. Bird, M. F. Grant, C. D. Mathias, and S. A. Owen, Trinity; O. V. Payne and C. M. Stevenson, St. John's; H. M. Clarke, Clare; G. T. Western, Pembroke; W. R. Higgins, W. Lowe, W. H. Thresher, and F. L. Woods, Caius; F. W. M. Palmer, Jesus; R. F. Moore, Christ's; R. Puttock, Emmanel; and E. W. Sheaf, Downing.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—T. H. Jones (Sections I. and II.), King's College Hospital; R. C. Richards (Section I.), University College Hospital; A. M. Walker (Sections I. and II.), Manchester; and J. M. Wall (Sections I. and II.), Westminster and St. Thomas's Hospitals.
Medicine.—J. B. Bradley (Section I.), [illegible] 'en, Bristol; T. H. Jones (Sections I. and [illegible] al; T. R. Roberts (Section II.), Londo [illegible] kes (Sections I. and II.), Leeds; and M. C. Vivian (Section I.), Royal Free Hospital.
Forensic Medicine.—A. B. Gosse and M. E. Jeremy, Royal Free Hospital; T. H. Jones, King's College Hospital; and J. H. K. Sykes, Leeds.
Midwifery.—C. G. Grey, St. Bartholomew's Hospital; M. E. Jeremy, Royal Free Hospital; T. H. Jones, King's College Hospital; A. M. Walker, Manchester; and P. C. West, St Thomas's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—P. F. Howden, M. E. Jeremy, T. H. Jones, and A. M. Walker.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. T. Tanja has been recognised as *privat-docent* of Internal Medicine.—*Berlin:* Dr. Max Martens, *privat-docent* of Surgery, has been granted the title of Professor.—*Brussels:* Dr. Brachet of Liège has been appointed to the chair of Anatomy, Dr. Sacré and Dr. Hauben, who have been Professors respectively of Systematic and Topographical Anatomy, having resigned.—*Cracow:* Dr. Alexander Bosovski, *privat-docent* of Surgery, has been promoted to an Extraordinary Professorship.—*Göttingen:* Dr. A. Pütter has been recognised as *privat-docent* of Physiology.—*Lemberg:* Dr. Leon Popielski of St. Petersburg has been appointed to the chair of Pharmacology and Pharmacognosis.—*Lyons:* Dr. Rollet has been promoted to the chair of Ophthalmology vacant by the death of Dr. Gayet.—*Munich:* Dr. Hans Gudden, *privat-docent* of Mental Diseases, has been promoted to an Extraordinary Professorship.—*Würzburg:* Dr. Wilhelm Weygandt, *privat-docent* of Mental Diseases, has been promoted to an Extraordinary Professorship.

UNIVERSITY OF OXFORD.—James Ritchie, M.A., B.Sc., M.D. Edin., reader in pathology, has been elected to an Ordinary Fellowship at New College.—Degree days for the present term are: Thursday, Jan. 26th; Thursday, Feb. 16th; and Thursday, March 16th.—The examination for a Radcliffe Travelling Fellowship will commence on Tuesday, Feb. 28th. Names must be sent in on or before Saturday, Feb. 11th. (Full particulars will be found in the *University Gazette* of Dec. 6th, 1904.)

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—In aid of the endowment of cots at this hospital (an institution which has "a reliable income of only £763" and which is now being rebuilt to accommodate 200 patients), a gigantic Christmas tree and children's fête with music will be held on Thursday, Feb. 2nd, from 3.30 to 6 P.M., at the Kensington Town-hall. The entertainment will be opened by the Mayor. The tree is to be illuminated by electricity and each child will receive at least one present. Tickets, 2*s.* 6*d.* each, by private sale only, on or before Feb. 1st, from the honorary secretary, 50, Albert Hall

Mansions, London, S W , or the honorary secretary, Royal Waterloo Hospital Ladies' Association, 16, Brook street (corner of New Bond street), W

ROYAL DENTAL HOSPITAL, LEICESTER SQUARE —This hospital has received a donation of £100 from the Worshipful Company of Goldsmiths

A CENTENARIAN —Mrs Pritchard Bembridge of Sidmouth, Devon, reached the age of 104 years on Jan 20th

UNIVERSITY COLLEGE, BRISTOL —The sixth annual dinner of the University College Colston Society will be held on Jan 31st under the presidency of the Right Hon Lewis Fry, with the Rev Dr Butler, Master of Trinity College Cambridge, and Sir Oliver Lodge Principal of the University of Birmingham as the guests of the evening The society was founded in 1899 for the purpose of perpetuating the memory of Edward Colston and assisting University College, Bristol, *in such a manner as the committee of the* society might approve Last year the sum of £400 was handed by the society to the building fund of the College The Government grant to the College for 1905 will be £2000, an increase of £800 compared with 1904
